

Machine Learning in Remote Sensing

Alexandre.Bevington@gov.bc.ca

March 3, 2022

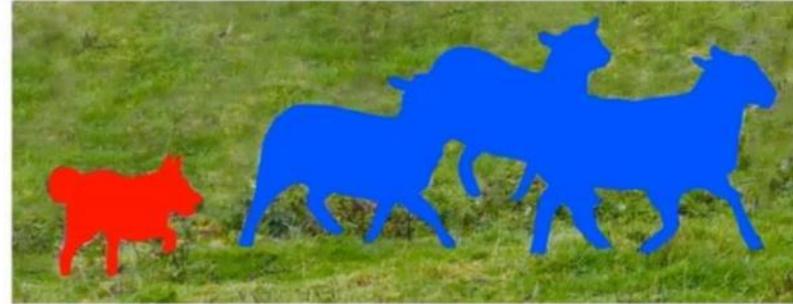

Why ML and RS?

- Many pixels / bands
 - E.g. Sentinel-2 images (100 x 100 km) for 13 bands (4x10m, 6x20m, 3x60m) = 558,333,333 data points = 750 MB
- Multiple data types
 - Terrain, lidar, hyperspectral, SAR
- Multi-temporal data
 - Timeseries, change detection, seasonal changes
- Large areas
 - Provincial, National, Global

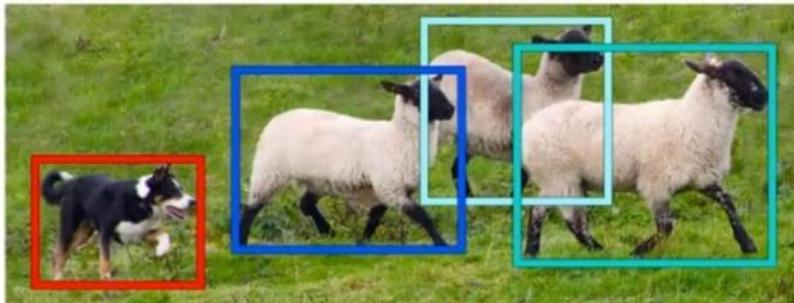

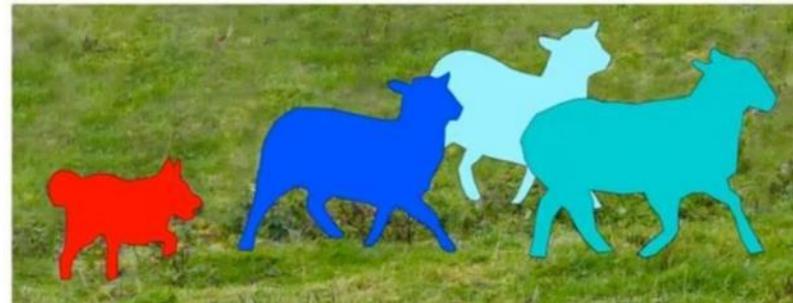

Image Recognition

Semantic Segmentation

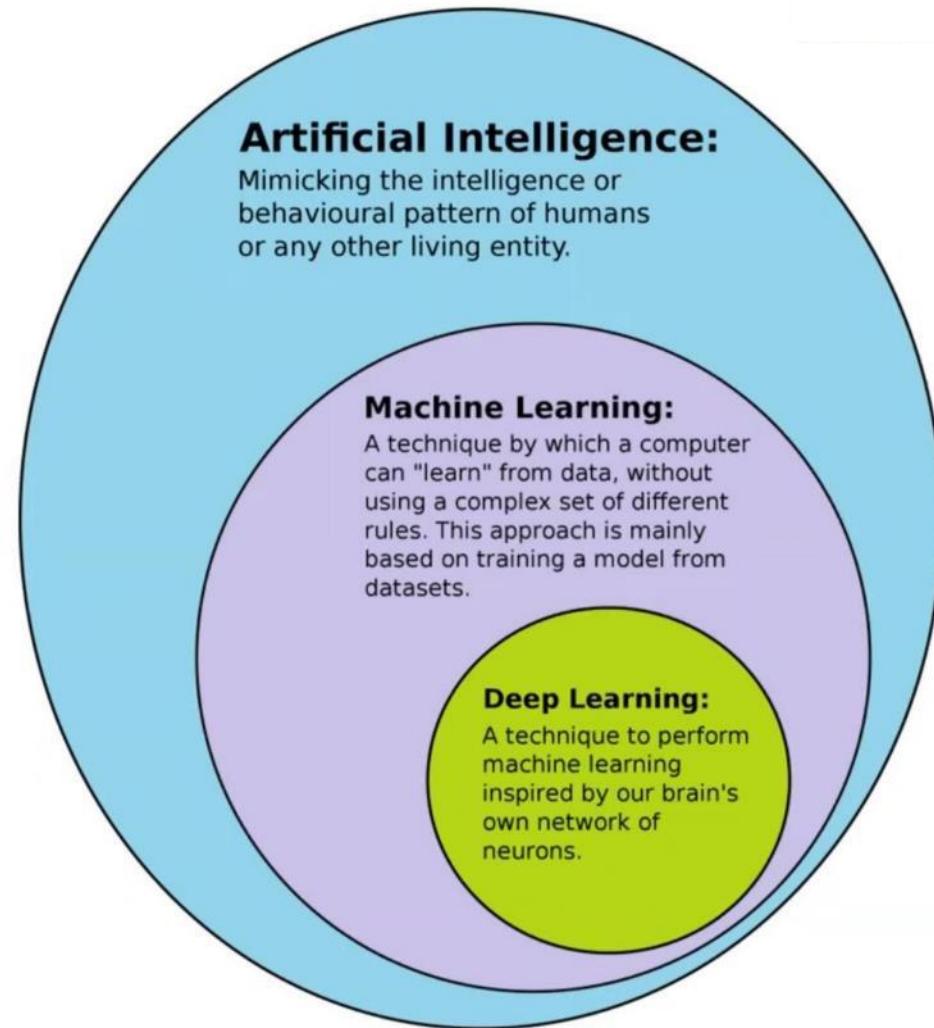

Object Detection

Instance Segmentation

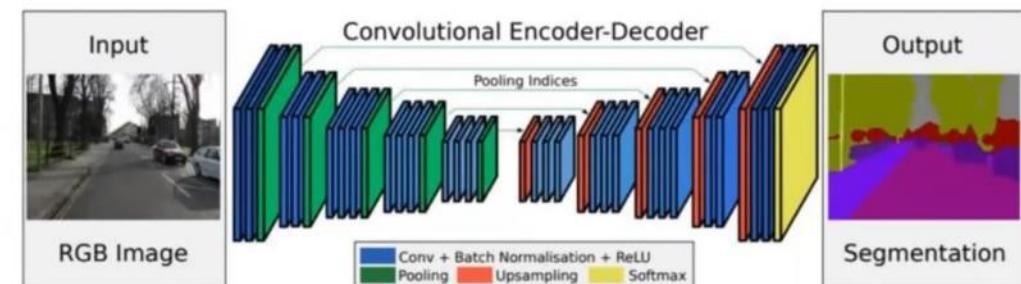

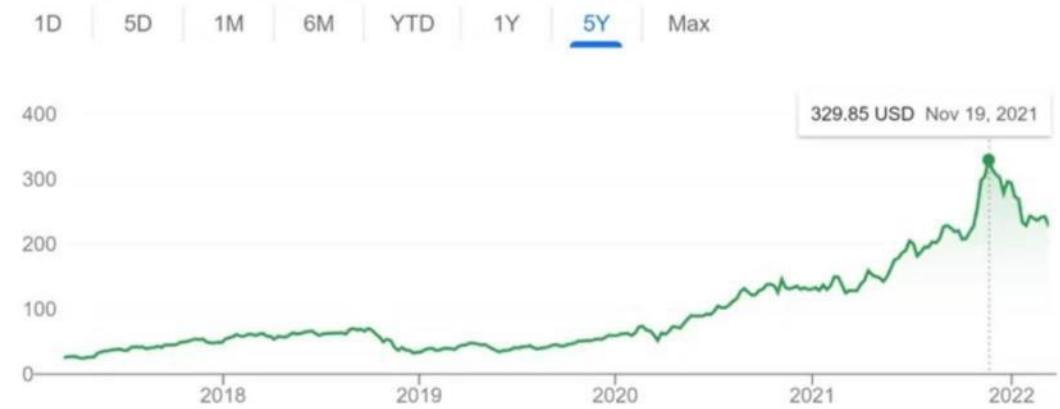

Deep Learning

- Extract patterns from data with learning algorithms
- Typically with the optimization of neural networks
- Challenge:
 - Training data!
 - Sensible questions!

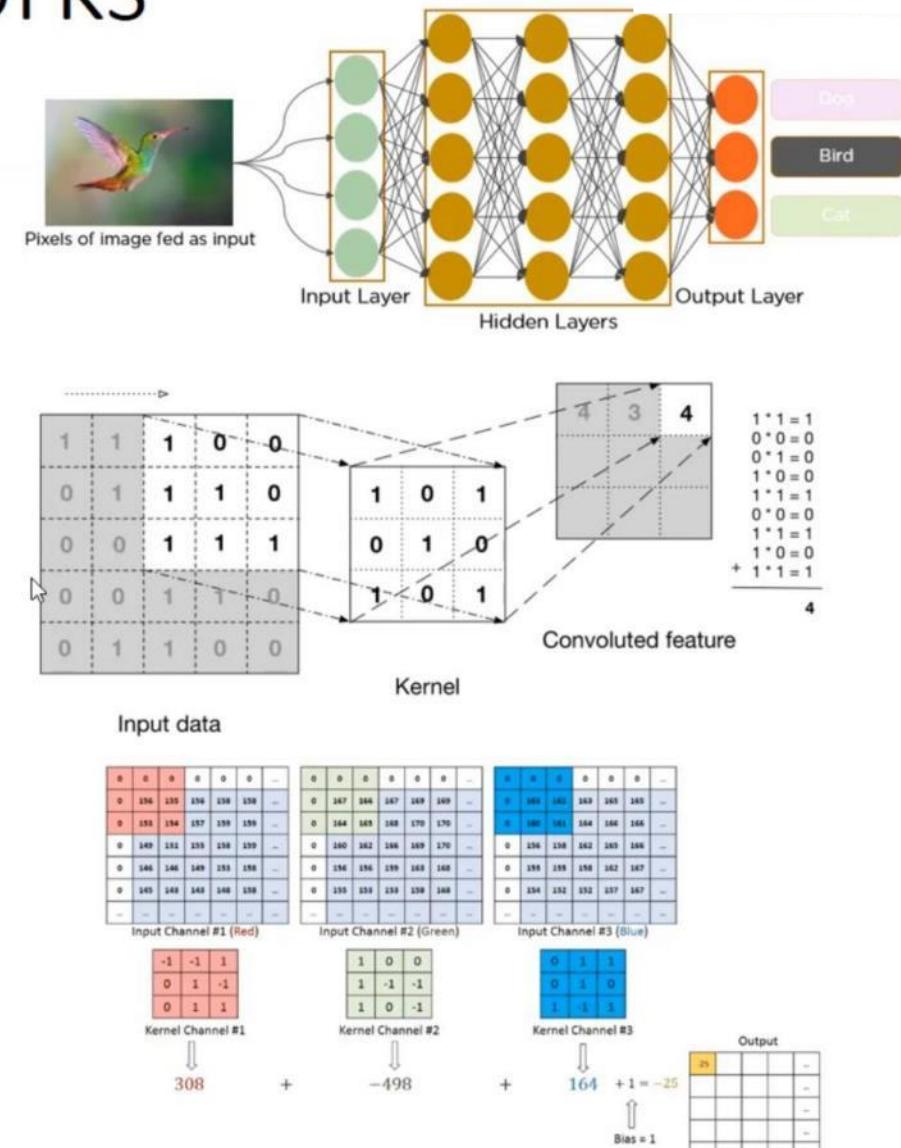

Why now

- We've always wanted to understand intelligence and create AI
- Problems are digital
- Moore's law
 - NVIA shares
 - High performance computing
- Open tools
 - GitHub
 - TensorFlow, Python and pyTorch
- Many models, non-expert usage
 - Convolutional neural network (CNN)
 - Multi-task learning technology (MTL)
 - Transfer learning technology (TL)

Convolutional neural networks

- Good for detecting patterns in images
- Model has convolutional (or hidden) layers
- CNNs reduce images so that they are easier to process
- Each layer receives input from previous layer, transforms them with filters/kernels, and outputs to next layer
- Convolutional layers can have 1 or more filters. User can specify the # of filters, the size of each filter (3×3 , 12×12 , 1×100), and the type of filter.
- Filter is moved around the entire image, or “convolved”, and calculate the dot/scalar products
 - First filters typically detect geometric attributes: edges, corners, circles, rectangles.
 - Deeper filters can detect specific objects (houses, roads, forest) and
 - Even deeper filters can understand complex land covers (airports, schools, hydroelectric dams).

Abstract

A large proportion of dryland trees and shrubs (hereafter referred to collectively as trees) grow in isolation, without canopy closure. These non-forest trees have a crucial role in biodiversity, and provide ecosystem services such as carbon storage, food resources and shelter for humans and animals^{1,2}. However, most public interest relating to trees is devoted to forests, and trees outside of forests are not well-documented³. Here we map the crown size of each tree more than 3 m² in size over a land area that spans 1.3 million km² in the West African Sahara, Sahel and sub-humid zone, using submetre-resolution satellite imagery and deep learning⁴. We detected over 1.8 billion individual trees (13.4 trees per hectare), with a median crown size of 12 m², along a rainfall gradient from 0 to 1,000 mm per year. The canopy cover increases from 0.1% (0.7 trees per hectare) in hyper-arid areas, through 1.6% (9.9 trees per hectare) in arid and 5.6% (30.1 trees per hectare) in semi-arid zones, to 13.3% (47 trees per hectare) in sub-humid areas. Although the overall canopy cover is low, the relatively high density of isolated trees challenges prevailing narratives about dryland desertification^{5,6,7}, and even the desert shows a surprisingly high tree density. Our assessment suggests a way to monitor trees outside of forests globally, and to explore their role in mitigating degradation, climate change and poverty.
