Map projections 1: principles

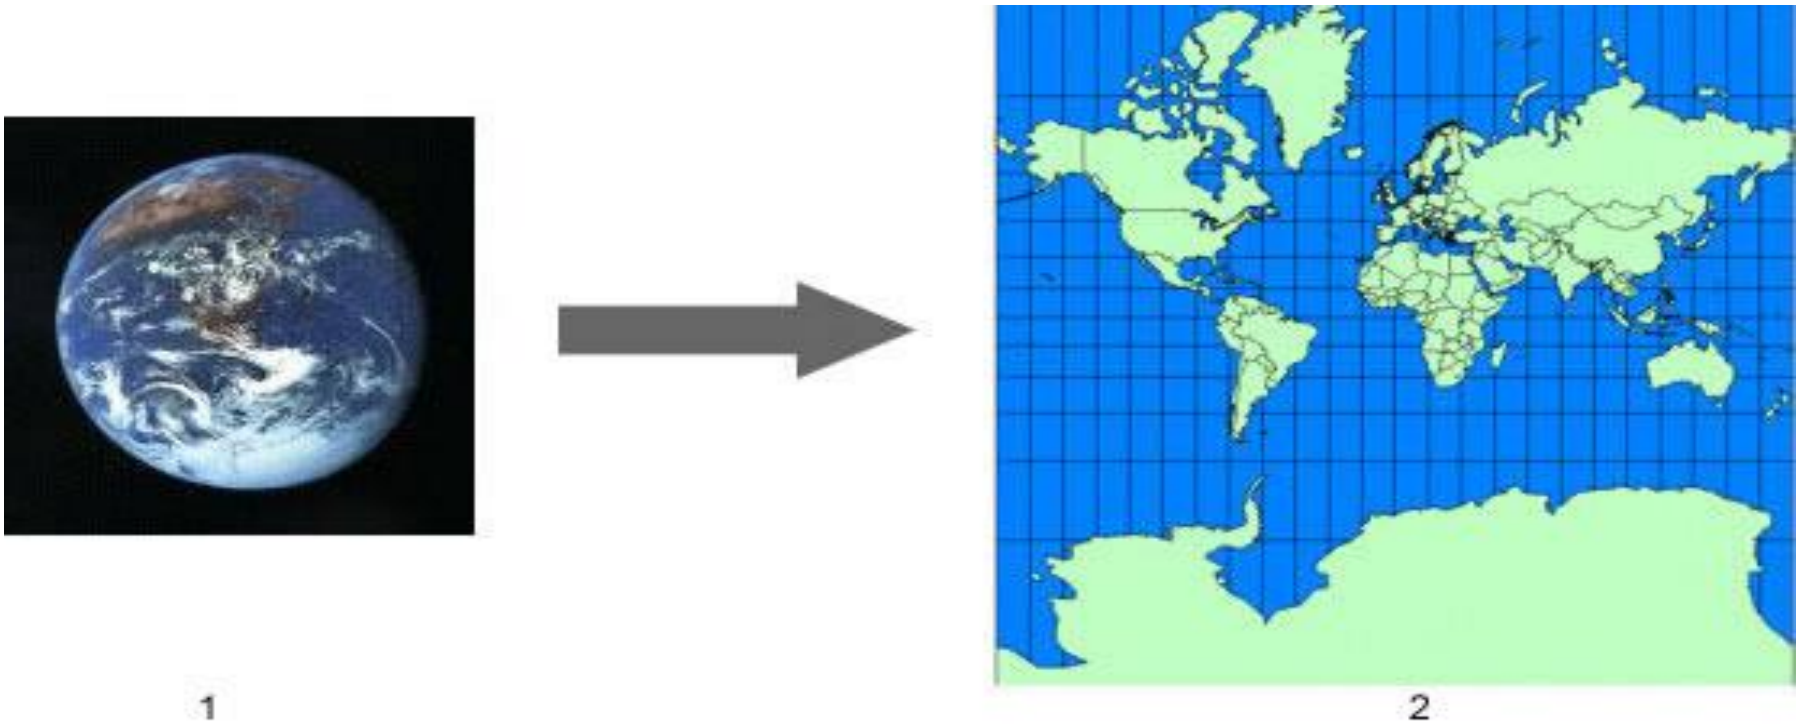
How can we 'project' a 3D globe onto a 2D display?

..only a globe maintains all spatial qualities without distortion

https://imgur.com/t/science_and_tech/53iqEMC

What is a Map Projection?

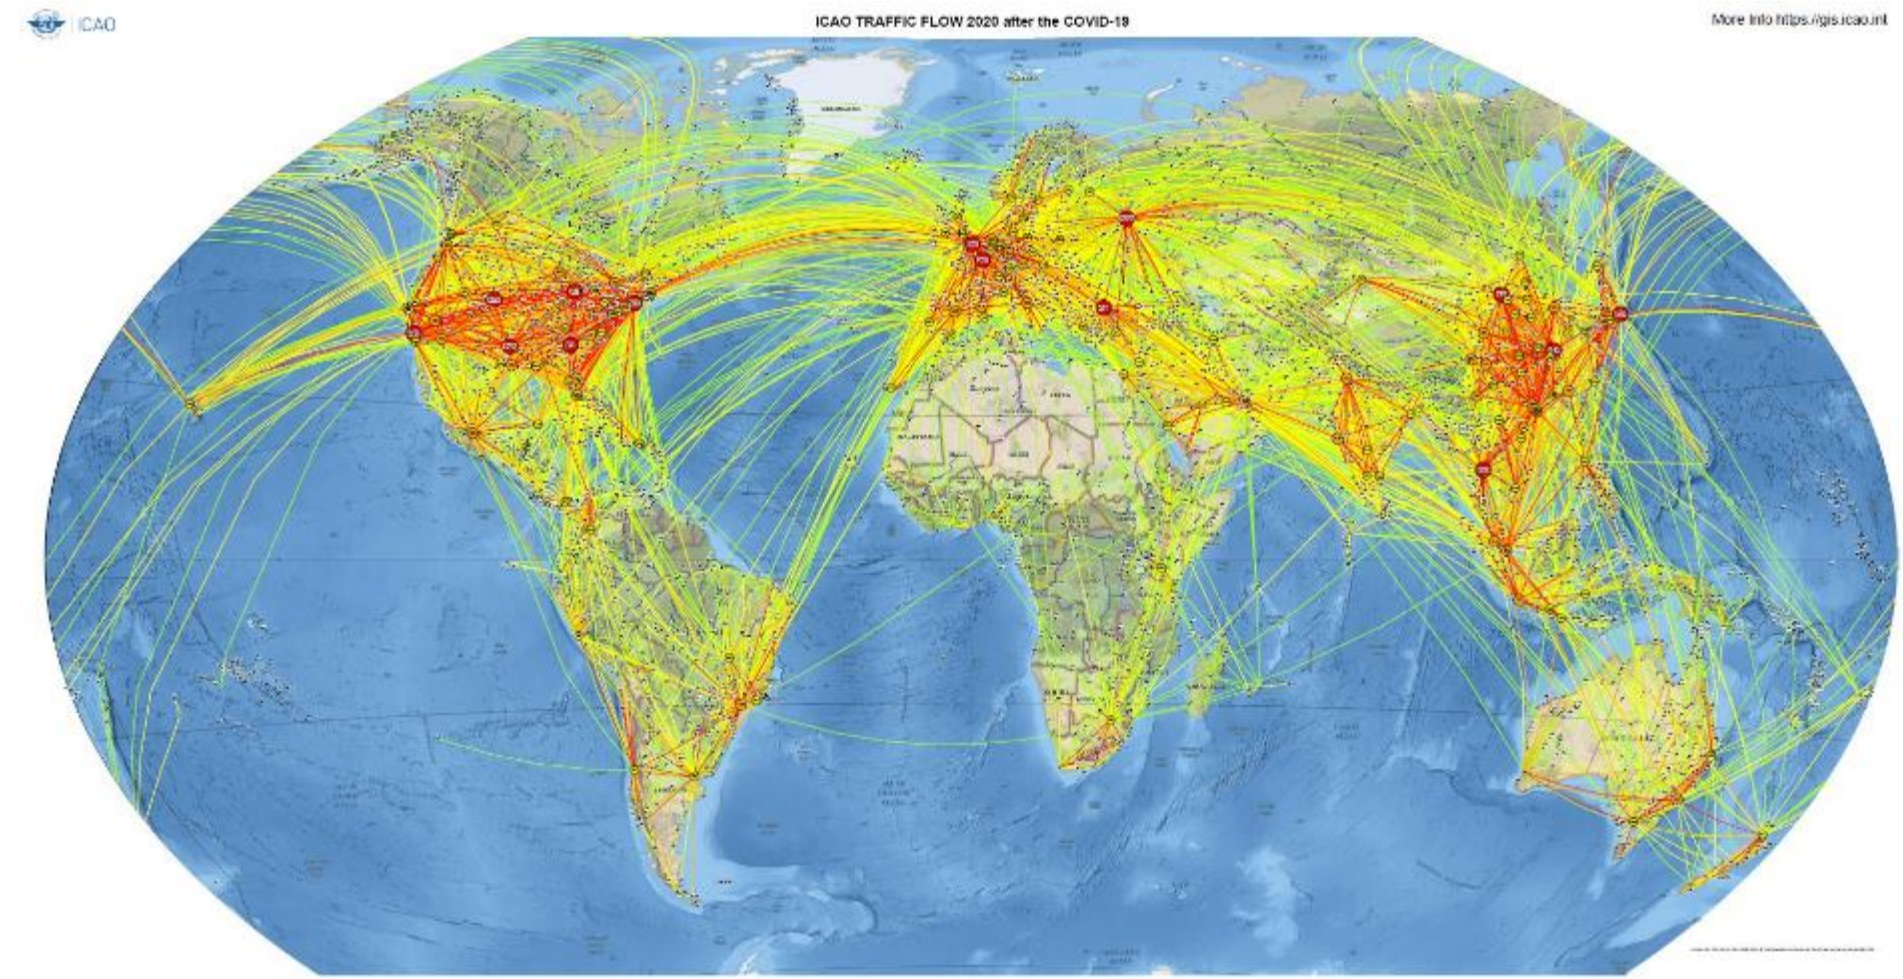
a mathematical expression giving the 3D surface on a 2D map



1 2

This process always results in distortion

Why don’t planes fly on straight lines – well they do …

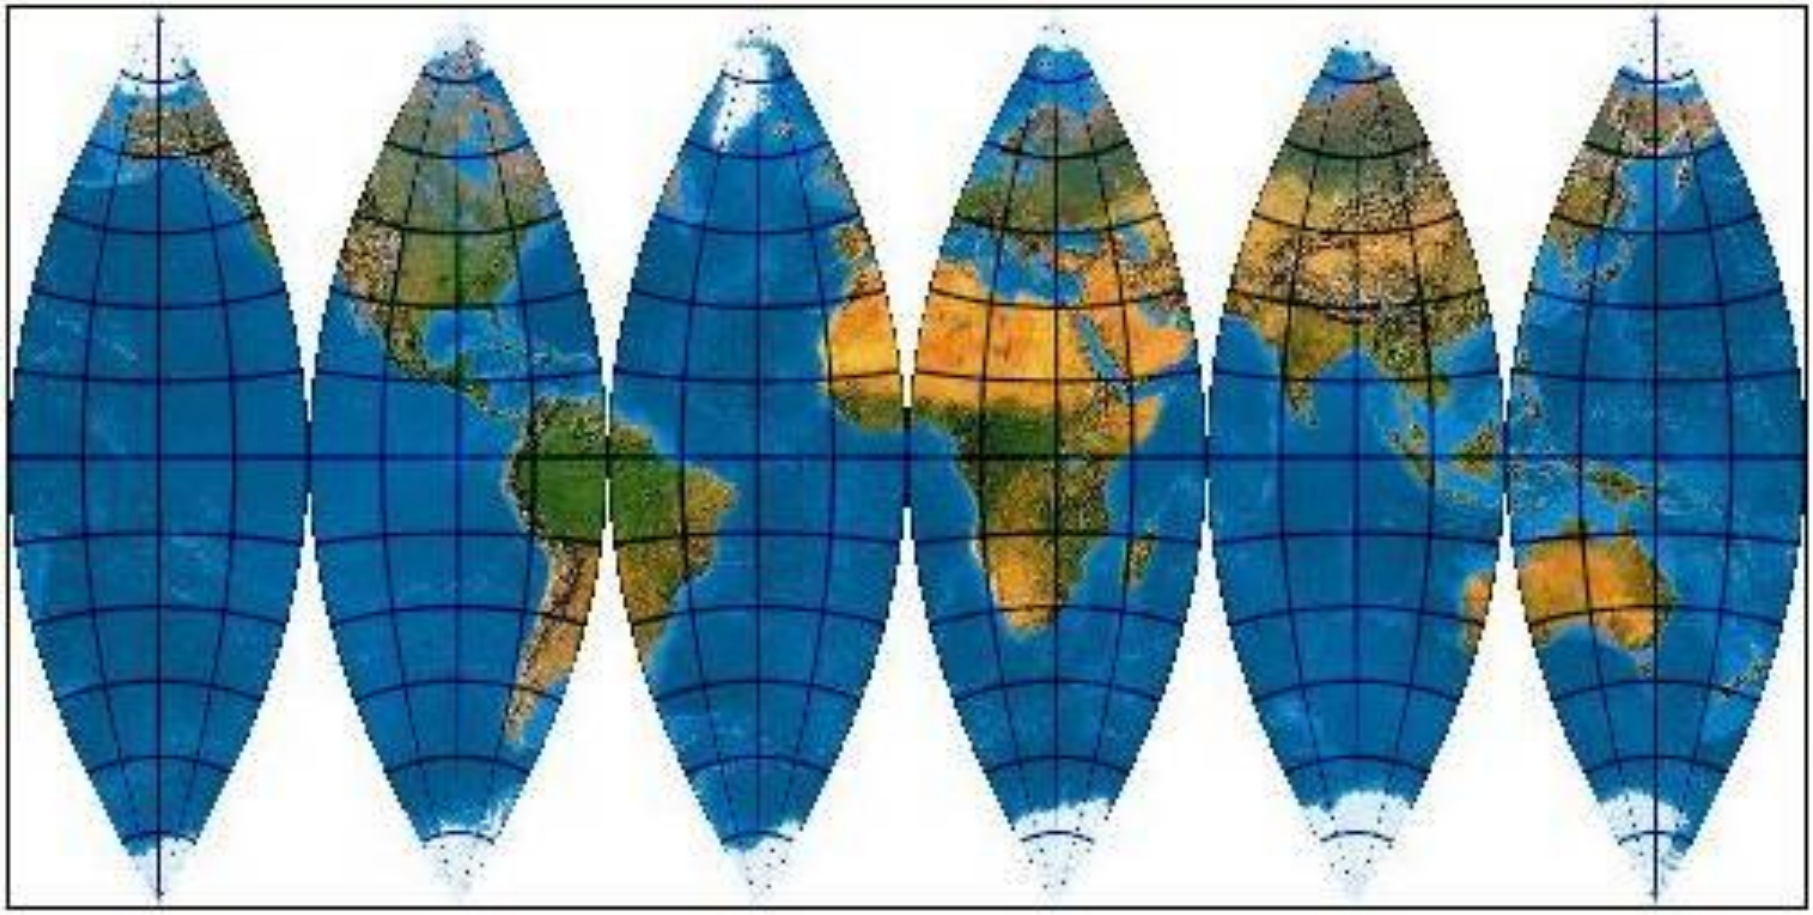


flight routes are 'great circles' … straight line in 3D space – but curves here

The world could be mapped like orange peel …

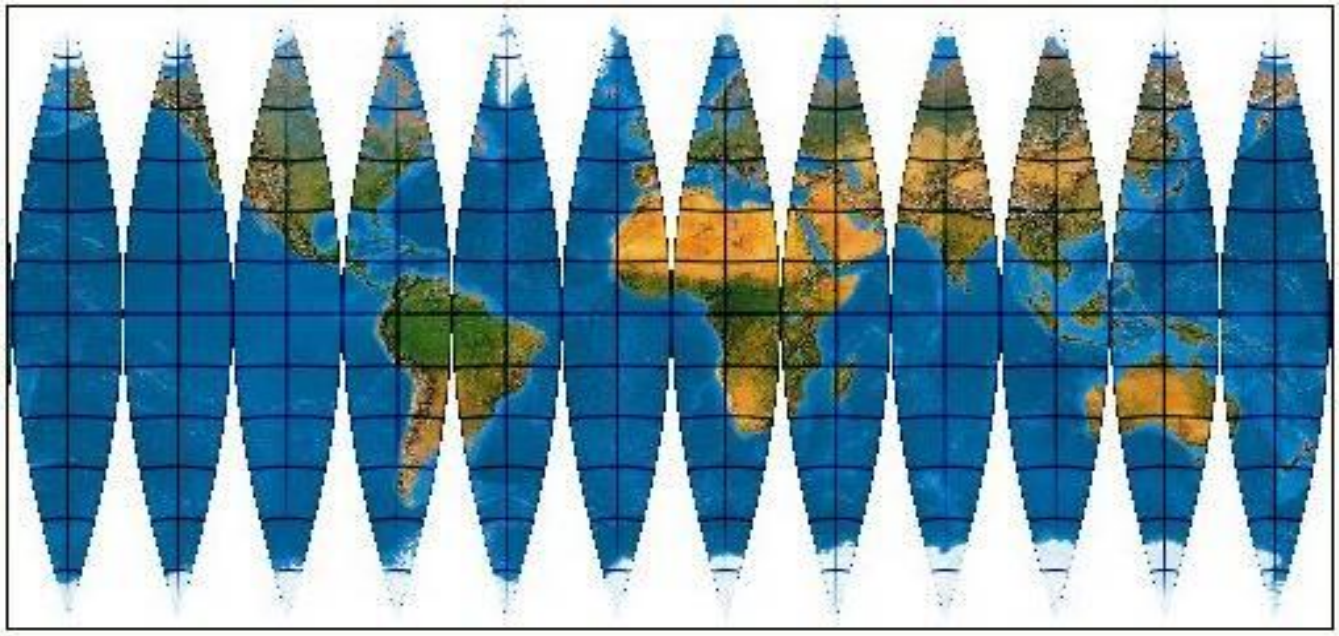
- not a problem locally, but it is for large areas

the strips would still have some curvature
.. and gaps between the strips



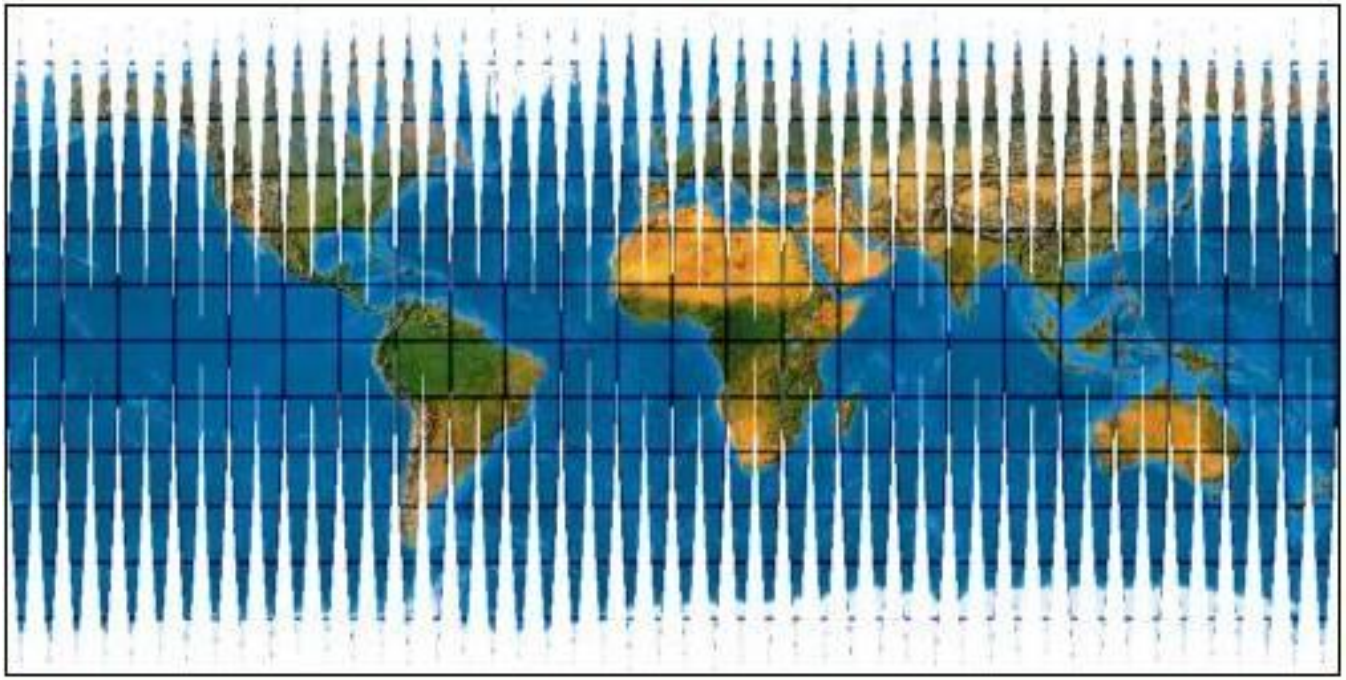
http://boehmwanderkarten.de/kartographie/is_netze_globussegmente.html

12 pieces



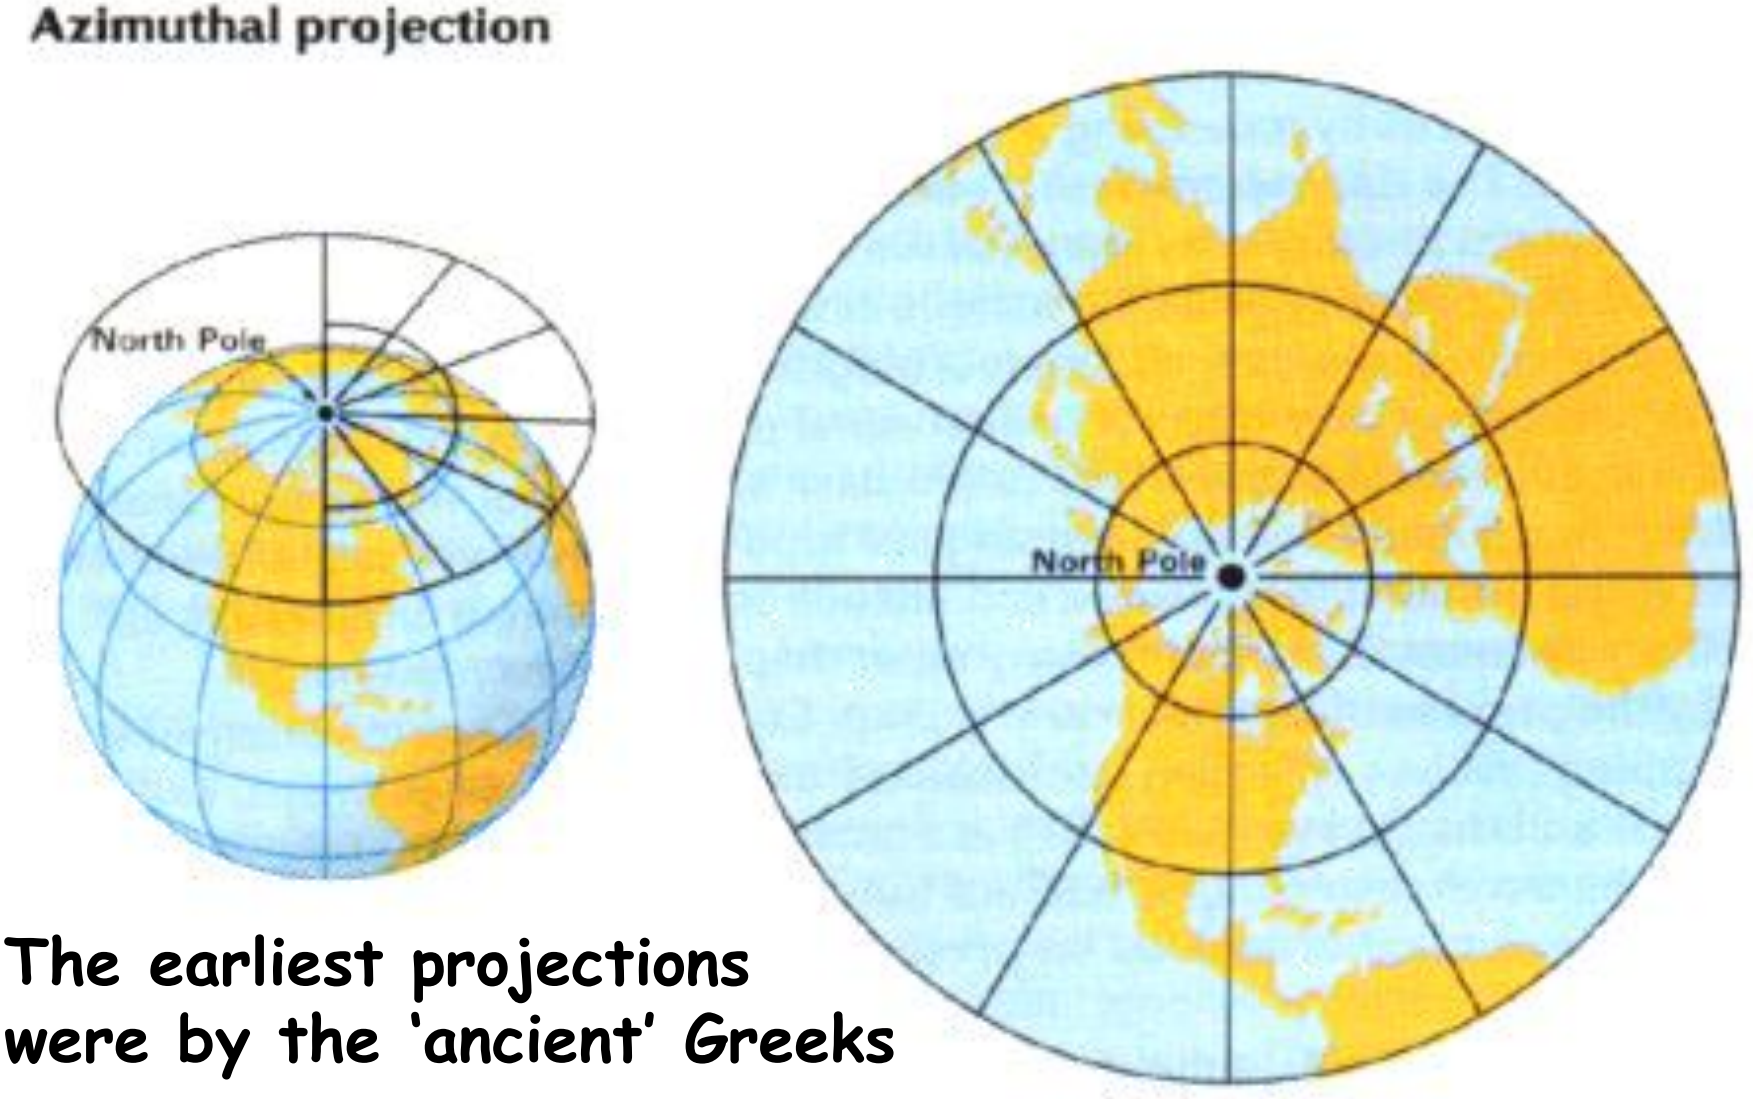
48 pieces

becoming like
UTM zones !



Or they can be made by literally 'projecting' the globe onto a map …

Azimuthal (planar) projections



The earliest projections were by the 'ancient' Greeks

Projection Terms

1. Scale Factor (SF)

SF = scale at any location /
divided by the 'principal scale'

e.g. if scale = 1:2 million and principal scale = 1:1 million

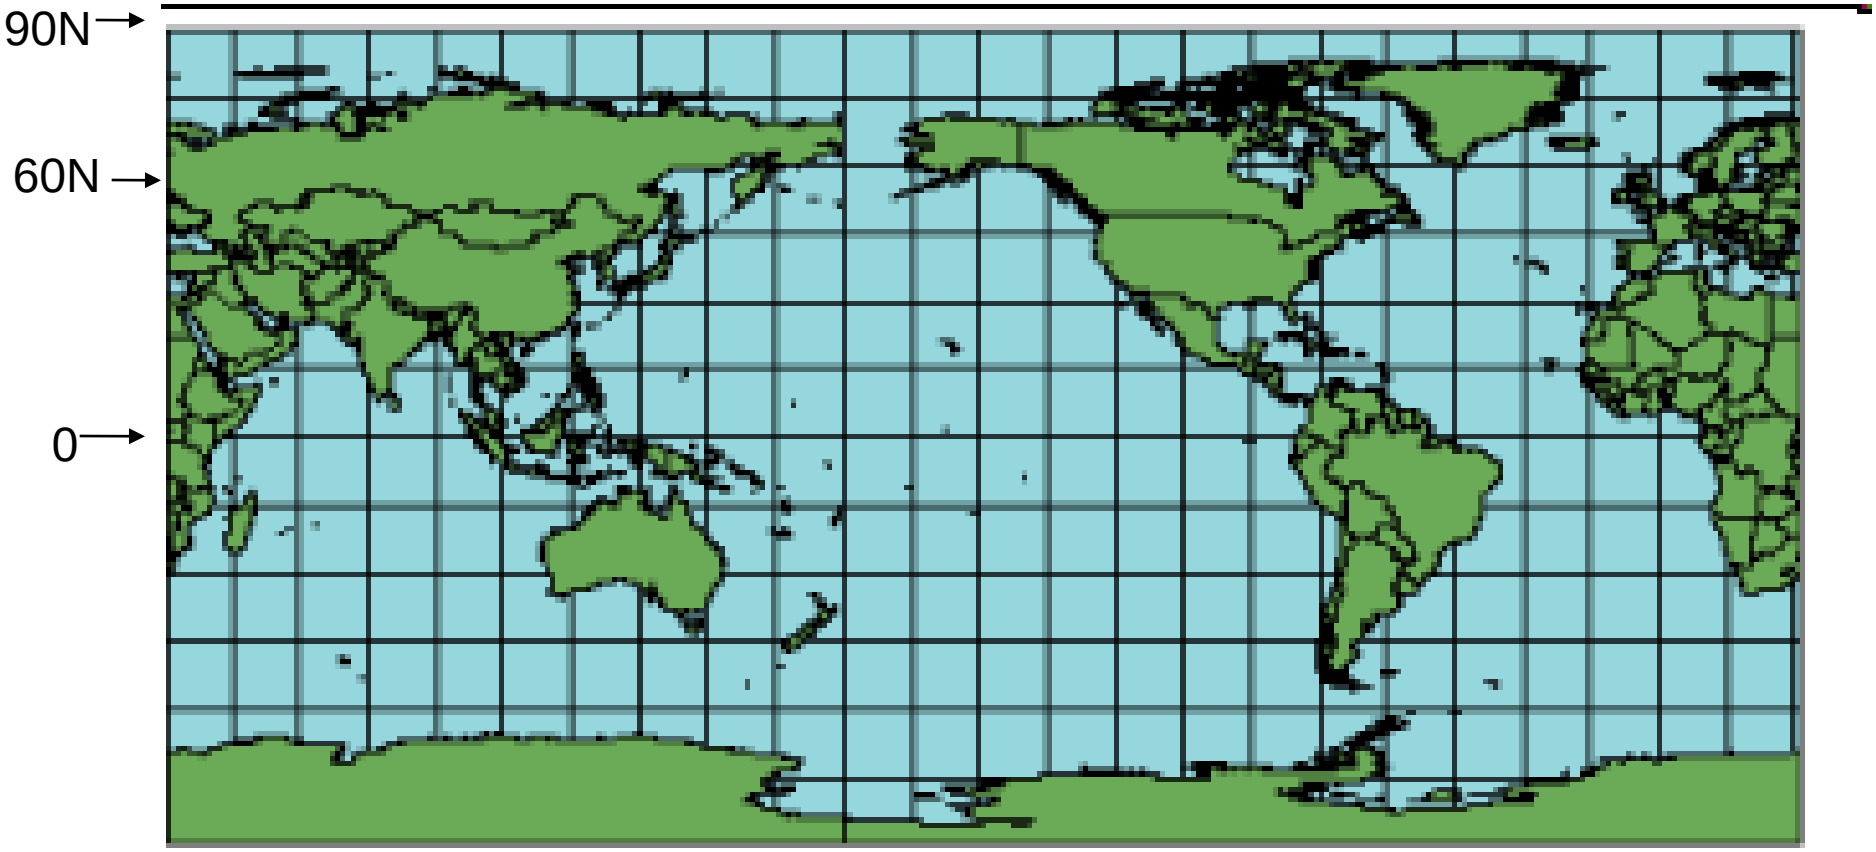
then SF at that point = 1/2million divided by 1/1million
= 1/2 (0.5)

Canadian NTS maps: 'scale factor 0.9996 at UTM zone edge'

Then Plate Carree projection
e.g. where every line of latitude is equal in length

SF along lines of latitude are: equator SF = 1;

at 60°N/S, SF =2 at 90°, SF = ∞ 'undefined'



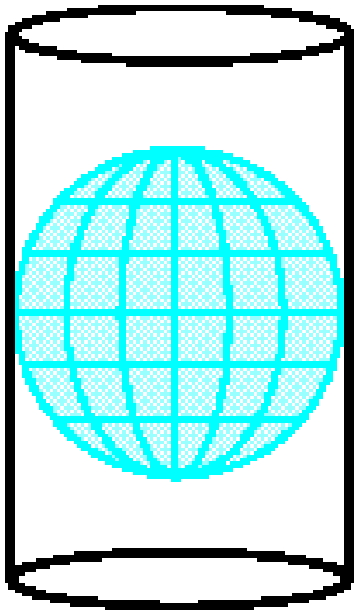
The SF in the other direction (along meridians) is 1

2. Developable surfaces:

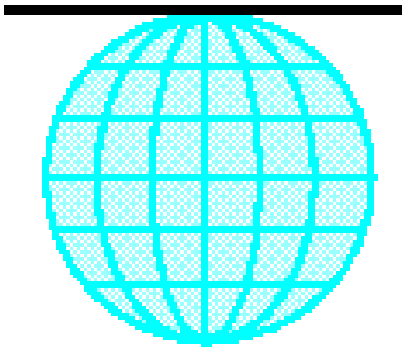
A two dimensional surface onto which the globe is projected

Conic

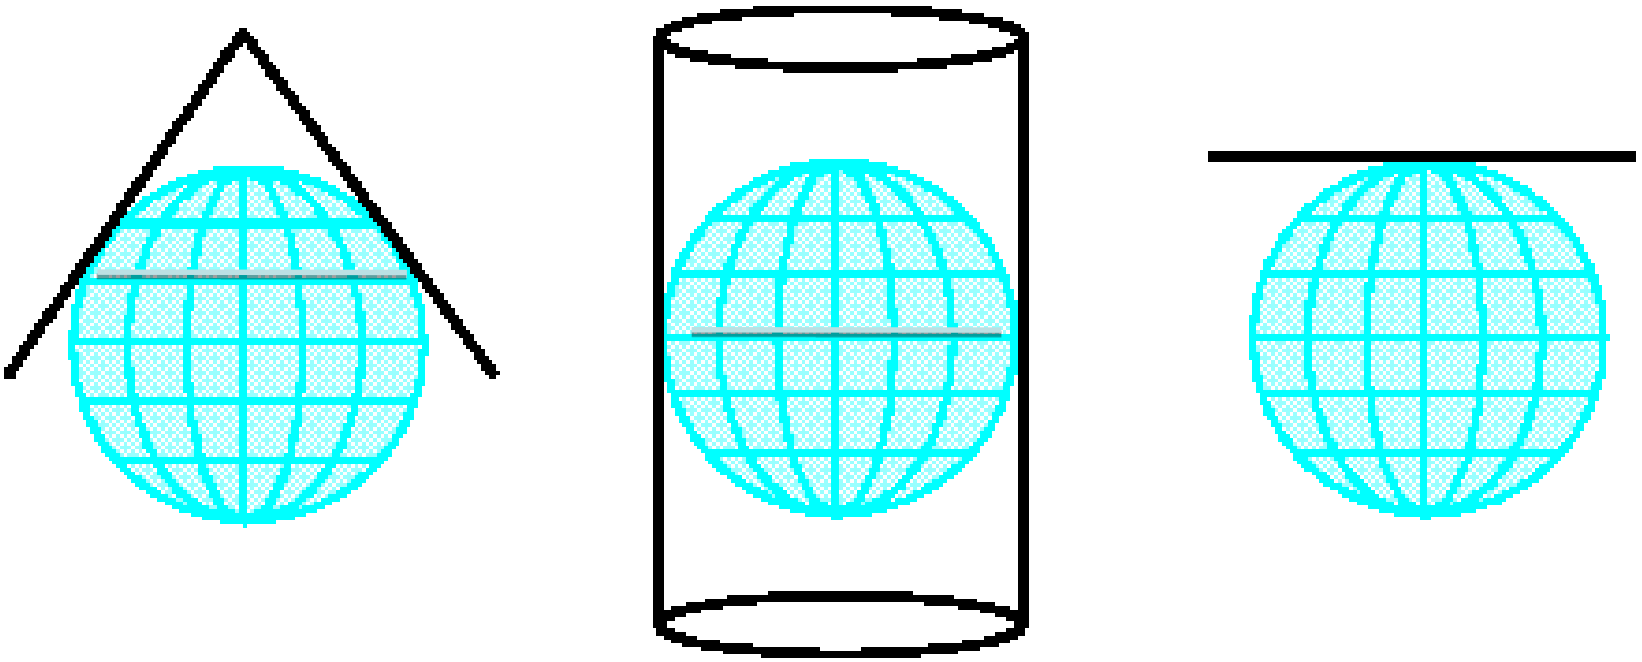
Cylindrical



Azimuthal (planar)



3. Standard Line



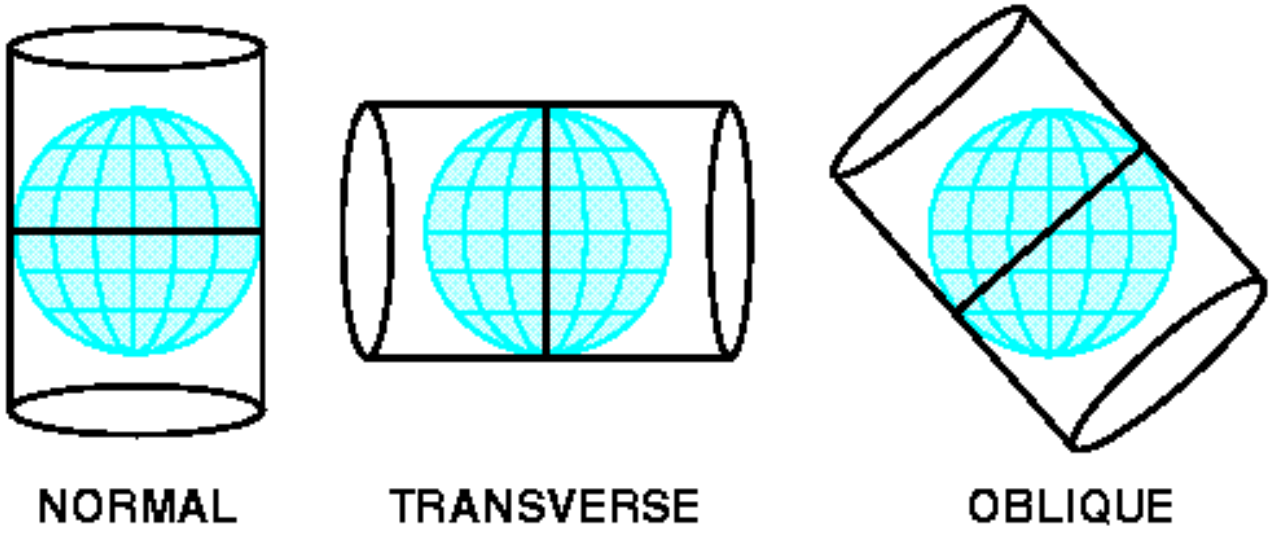
Distortion increases with distance between the 'globe' and the surface

The standard line has a scale factor = 1

(it is often the line of contact)

4. **Drawing of Projection Orientation**

Cylindrical projections:



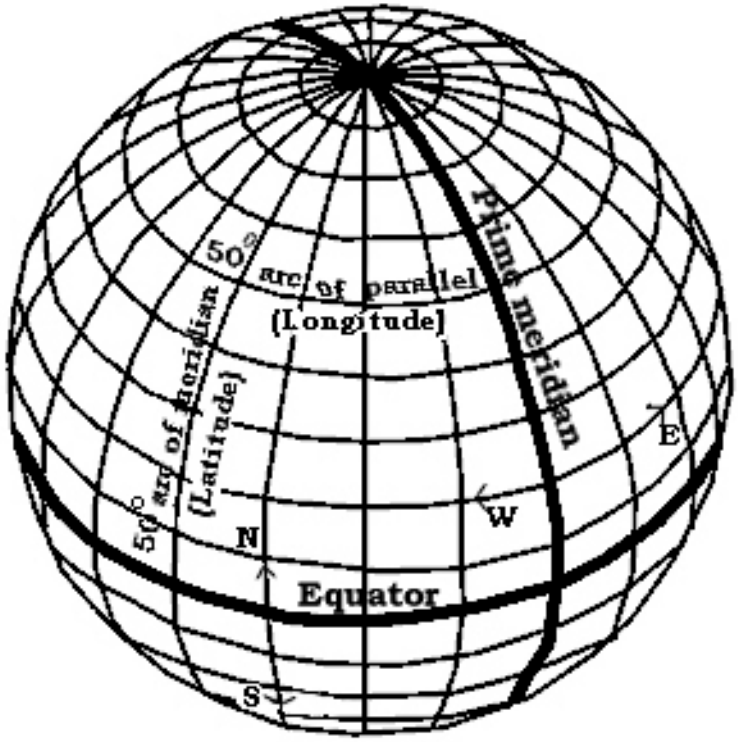
Planar projections aspects:

5. Distortion: …. compare to the graticule:

- Lines of latitude are 'parallel' and evenly spaced.

- Meridians converge at the poles, (half the distance at 60° N/S).

- Scale factor is 1 in all directions.



6. Projection properties

A projection can preserve

- **Shapes** **or**
- **Areas** **or**
- **Distances (but not all)**

…..but never more than one of these

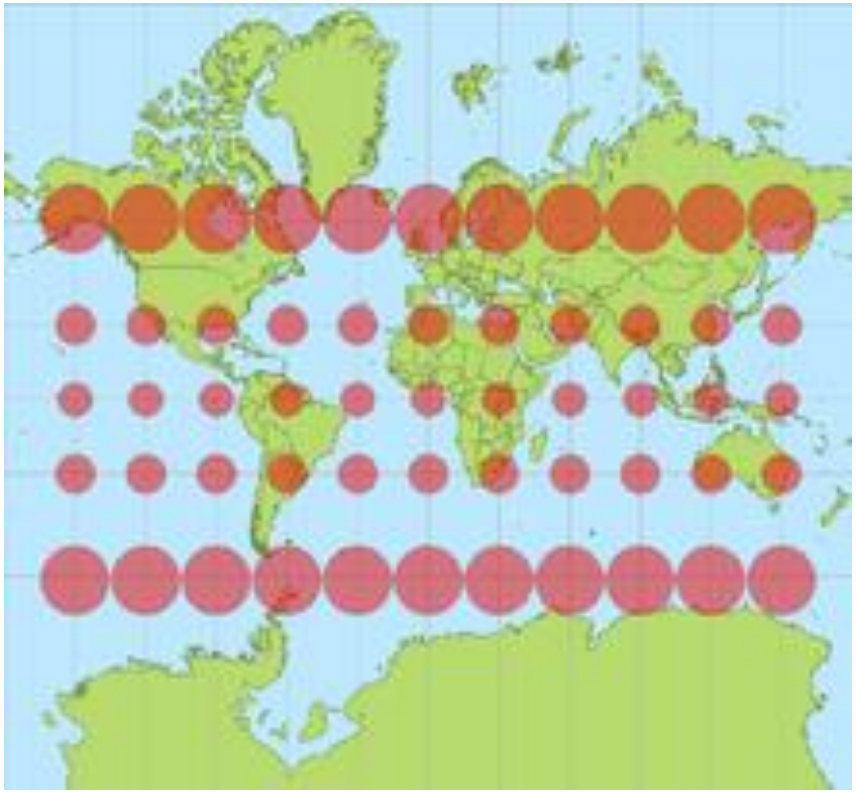
a. Shape

A projection that maintains shape is '**conformal**'

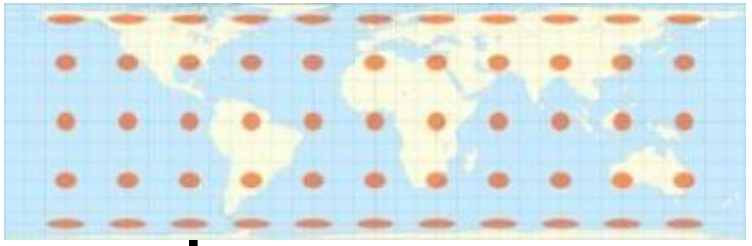
For example a 2x2 square becomes a 1x1 or 4x4 square. Stretching in one direction is **matched** by stretching in the other: that is, the scale factors are equal at a point in the two directions (i.e. there is 'equal-stretching').

Circles ("Tissot's Indicatrix") ->

These indicate the relative area compared to a standard area at the equator (the standard line)



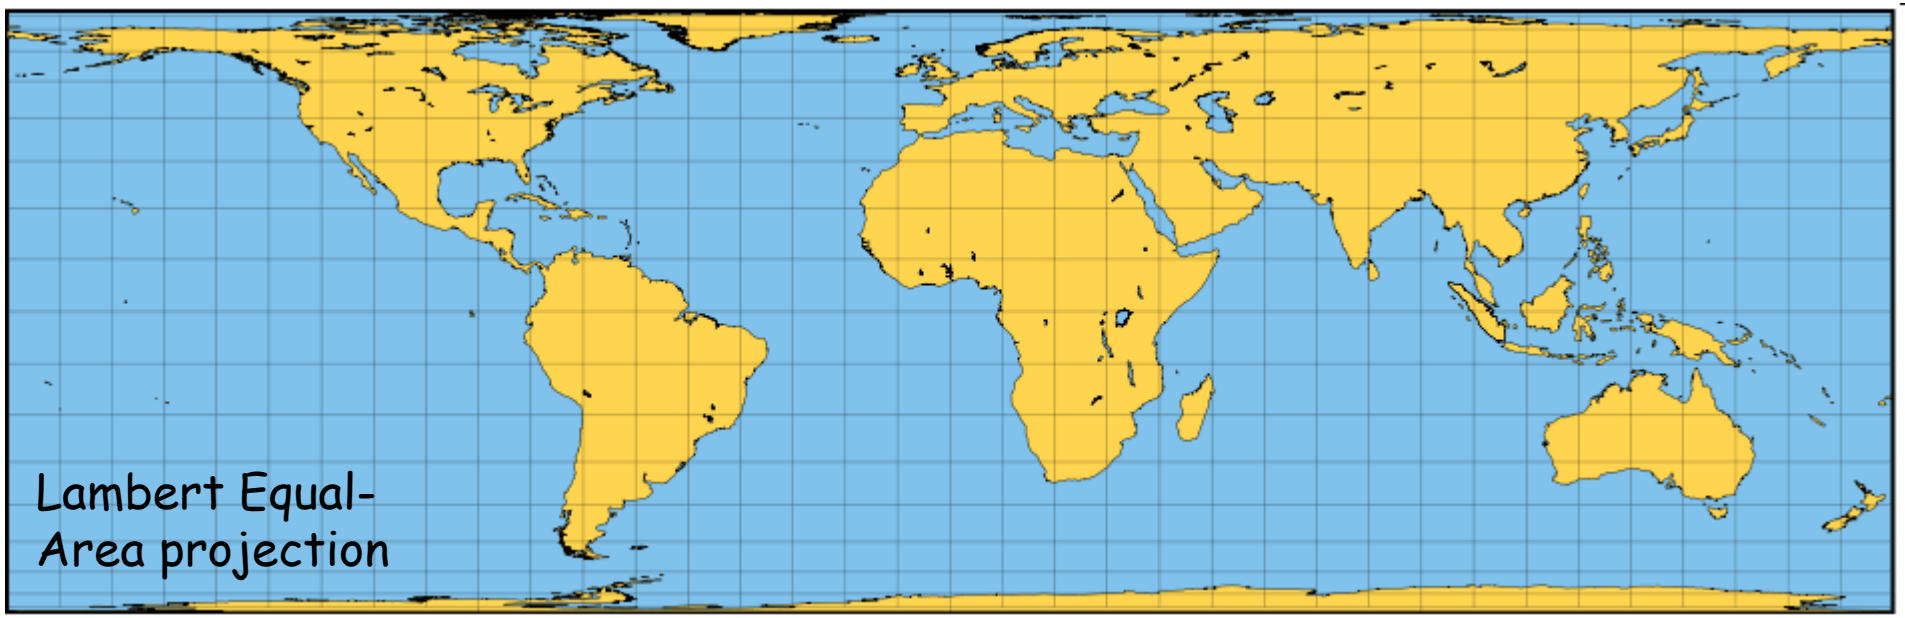
b. Area



A projection that maintains area is **equal area**

This is achieved by sacrificing **shape**: stretching in one direction to counter for earth curvature must be **compensated** by compression in the other.

In other words, the product of the two Scale factors at any point in the two directions (N-S and E-W) = 1.0 (e.g 1 x 1, 2 x 0.5 etc..)



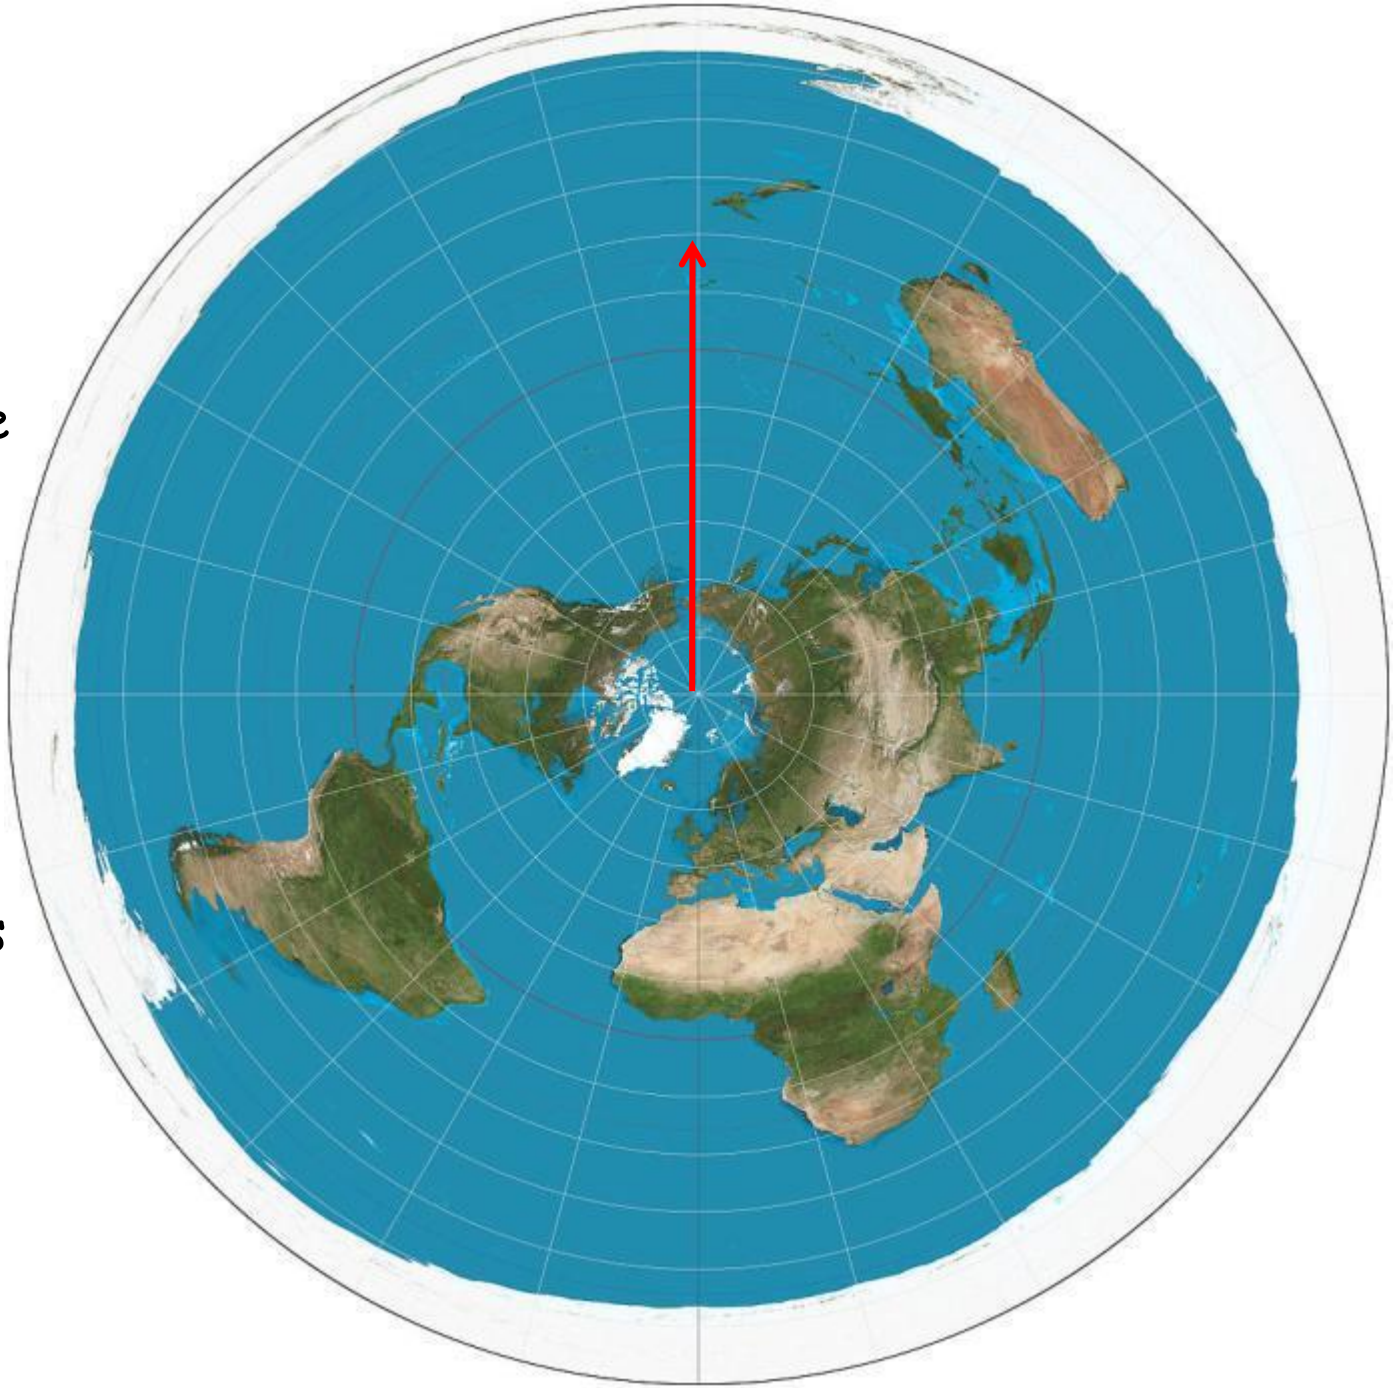
Hence a projection CANNOT preserve both shape AND area

(equal versus compensating stretching)

Projection properties: c. Distance

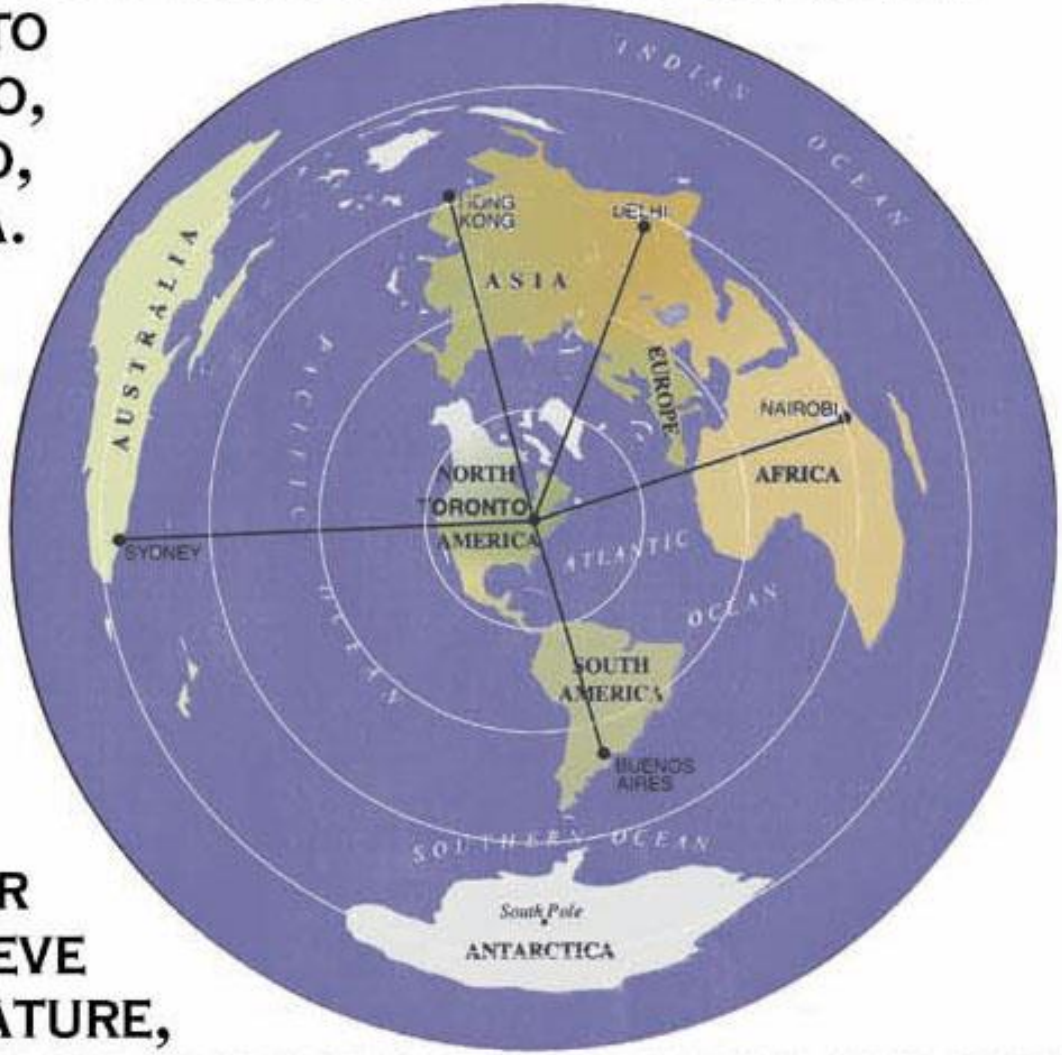
Distances can be correct in one direction from a line or in <u>all directions from a point</u>

In these cases, the projection is '**equidistant**'



Azimuthal equidistant

GUELKE'S EQUIDISTANT PROJECTION TELLS YOU EXACTLY HOW FAR IT IS FROM ANYWHERE ON EARTH TO TORONTO, ONTARIO, CANADA.

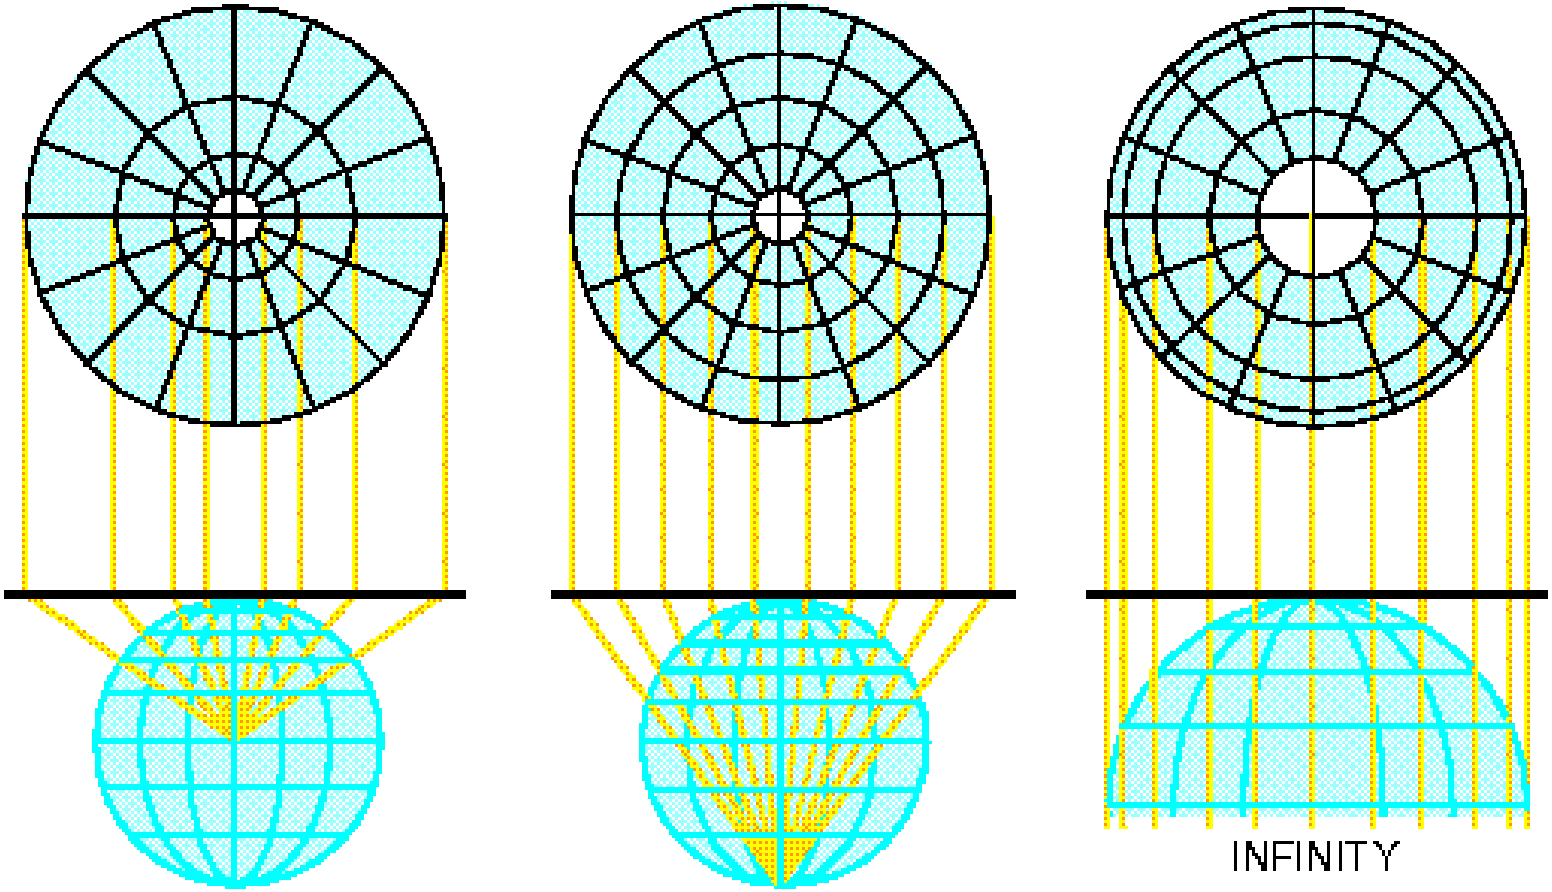


IN ORDER TO ACHIEVE THIS FEATURE, YOU NEED TO SACRIFICE SOME SHAPES AND SIZES.

www.diversophy.com/guelke.htm

Projection types (based on the developable surface)

I. Azimuthal projections



GNOMONIC

Great circles= straight lines

Thales 500BC

STEREOGRAPHIC

Conformal (shape)

Ptolemy 125BC

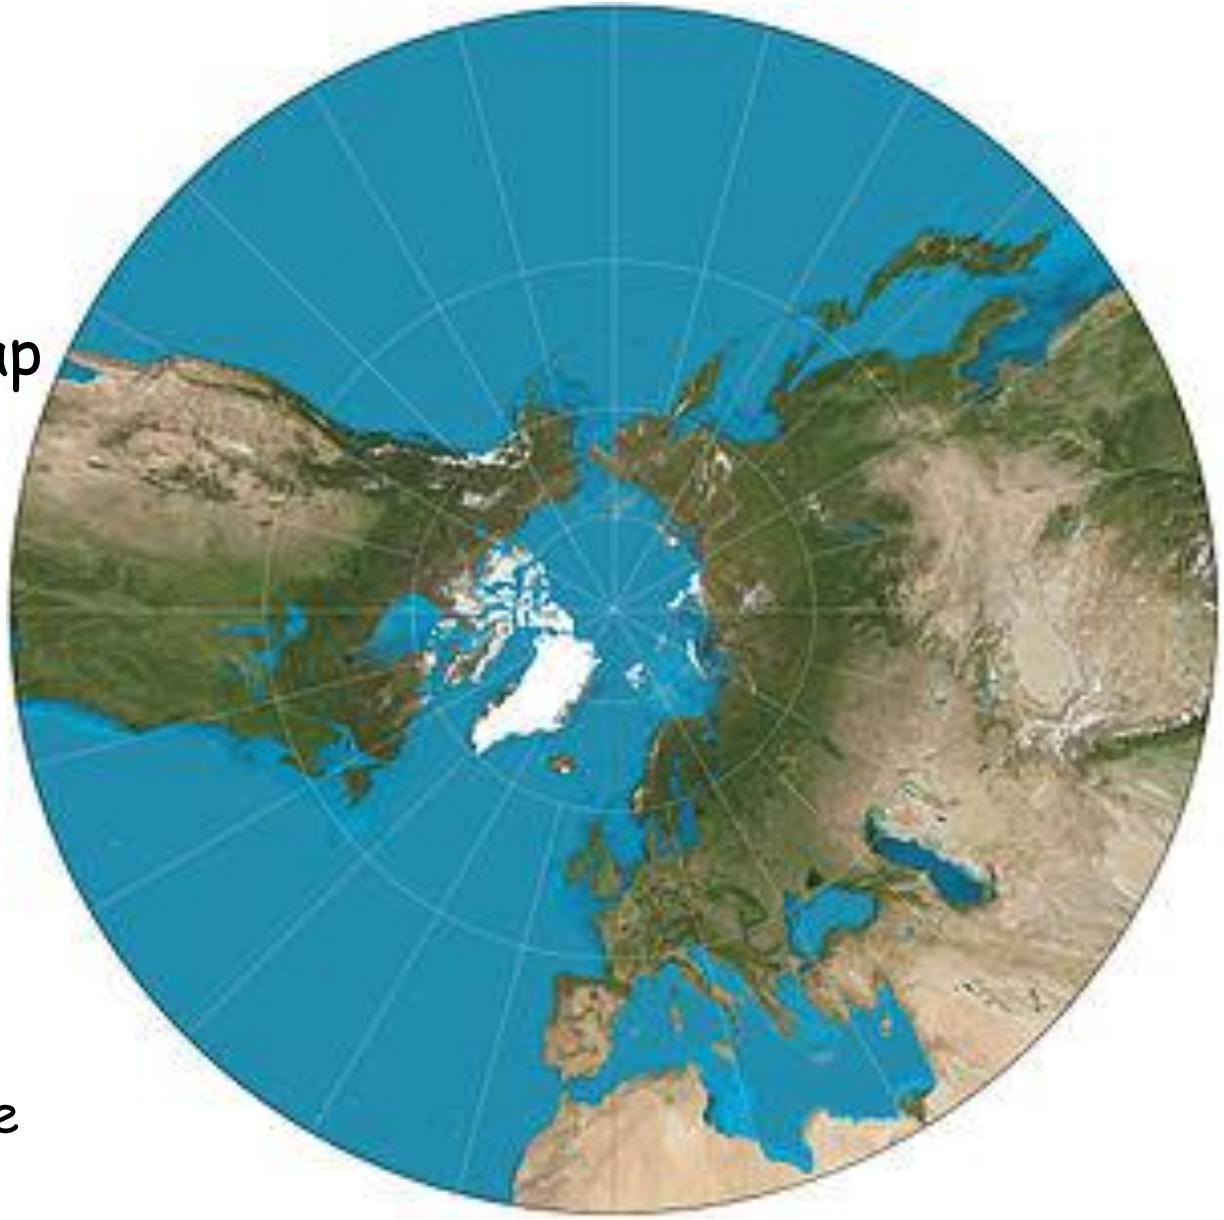
ORTHOGRAPHIC

'View from space'

Hipparchus 150BC

Gnomonic projection

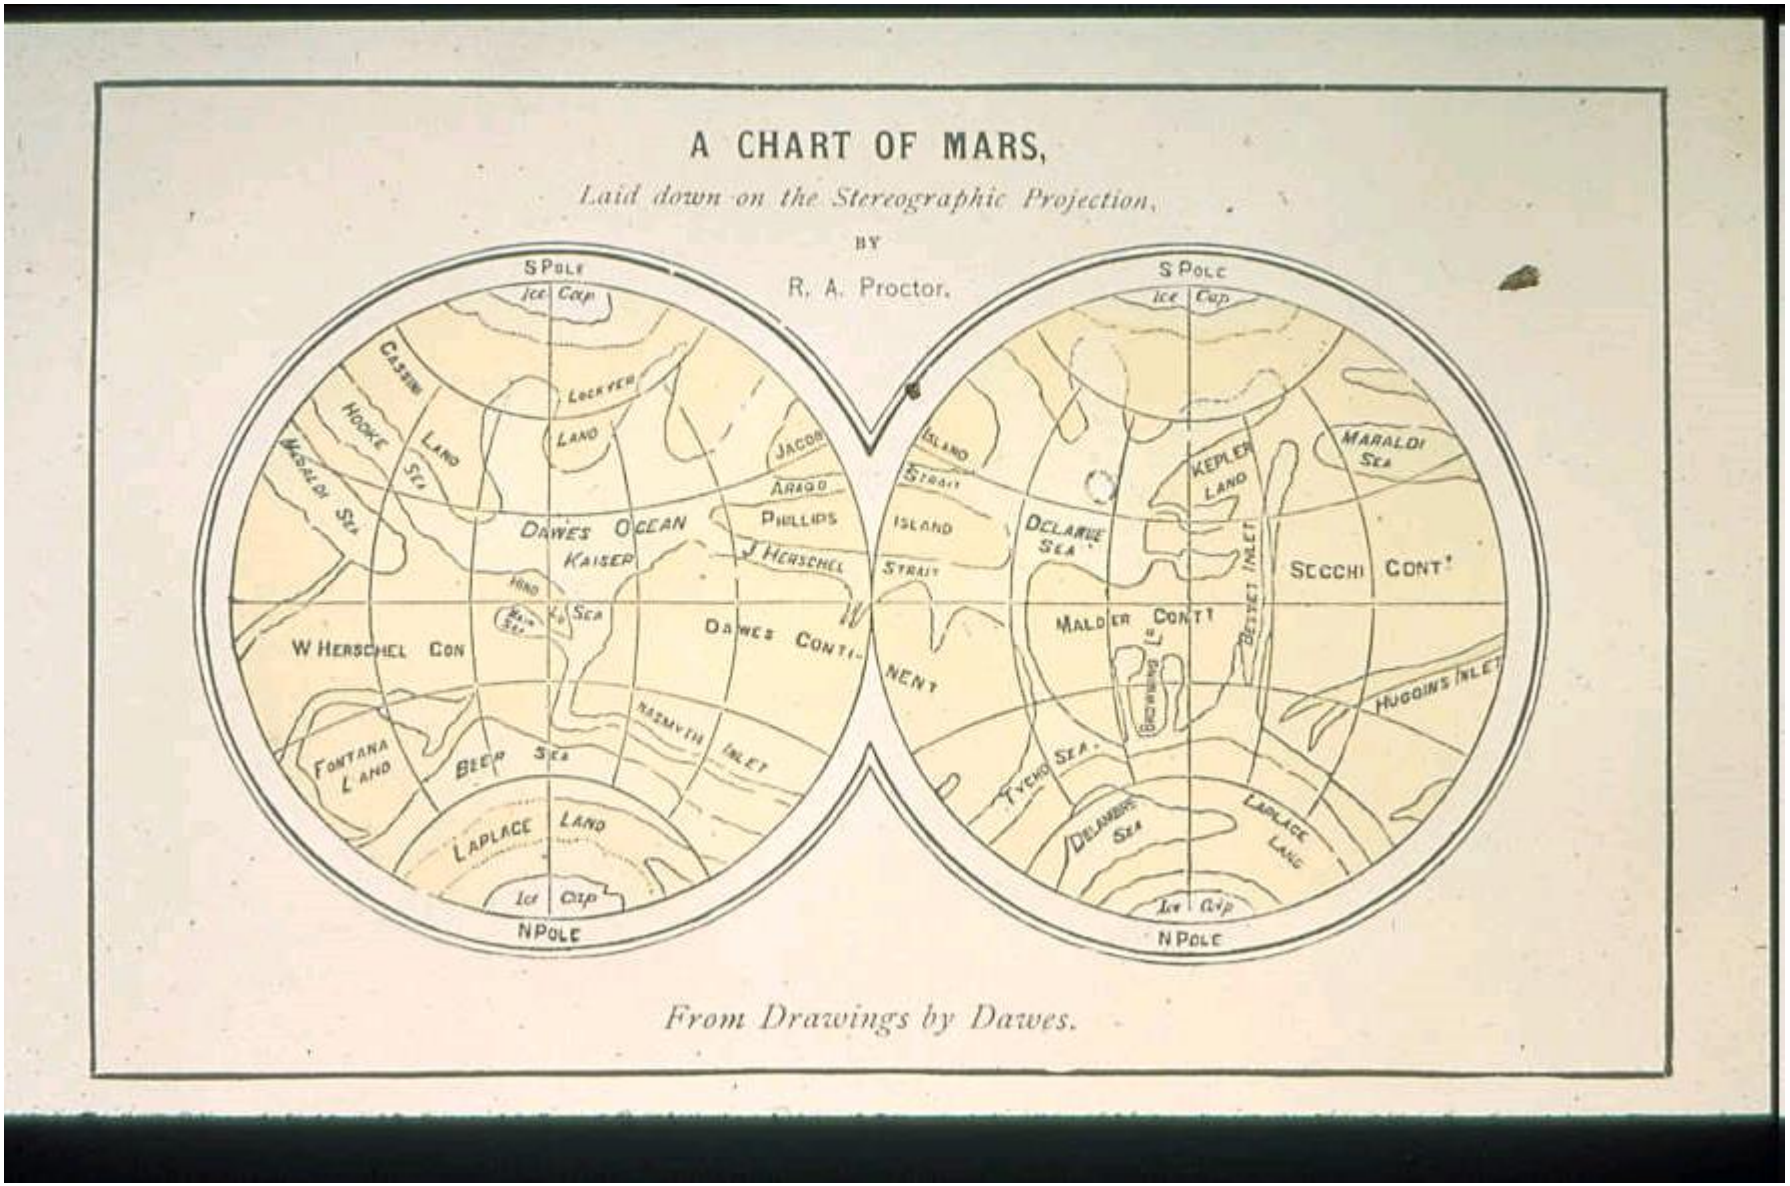
Probably the world's oldest map projection – 6th century BC



– the only one that shows all great circles as straight lines

(but cannot show one entire hemisphere)

First map of Mars, 1867- equatorial stereographic

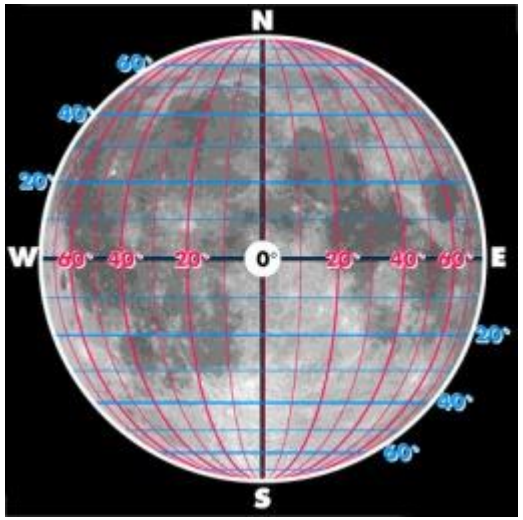


Dark / light = land / 'sea' .. Lines were called 'canals' … names from geography

Photomosaic 1960 (pre-NASA): Orthographic projection

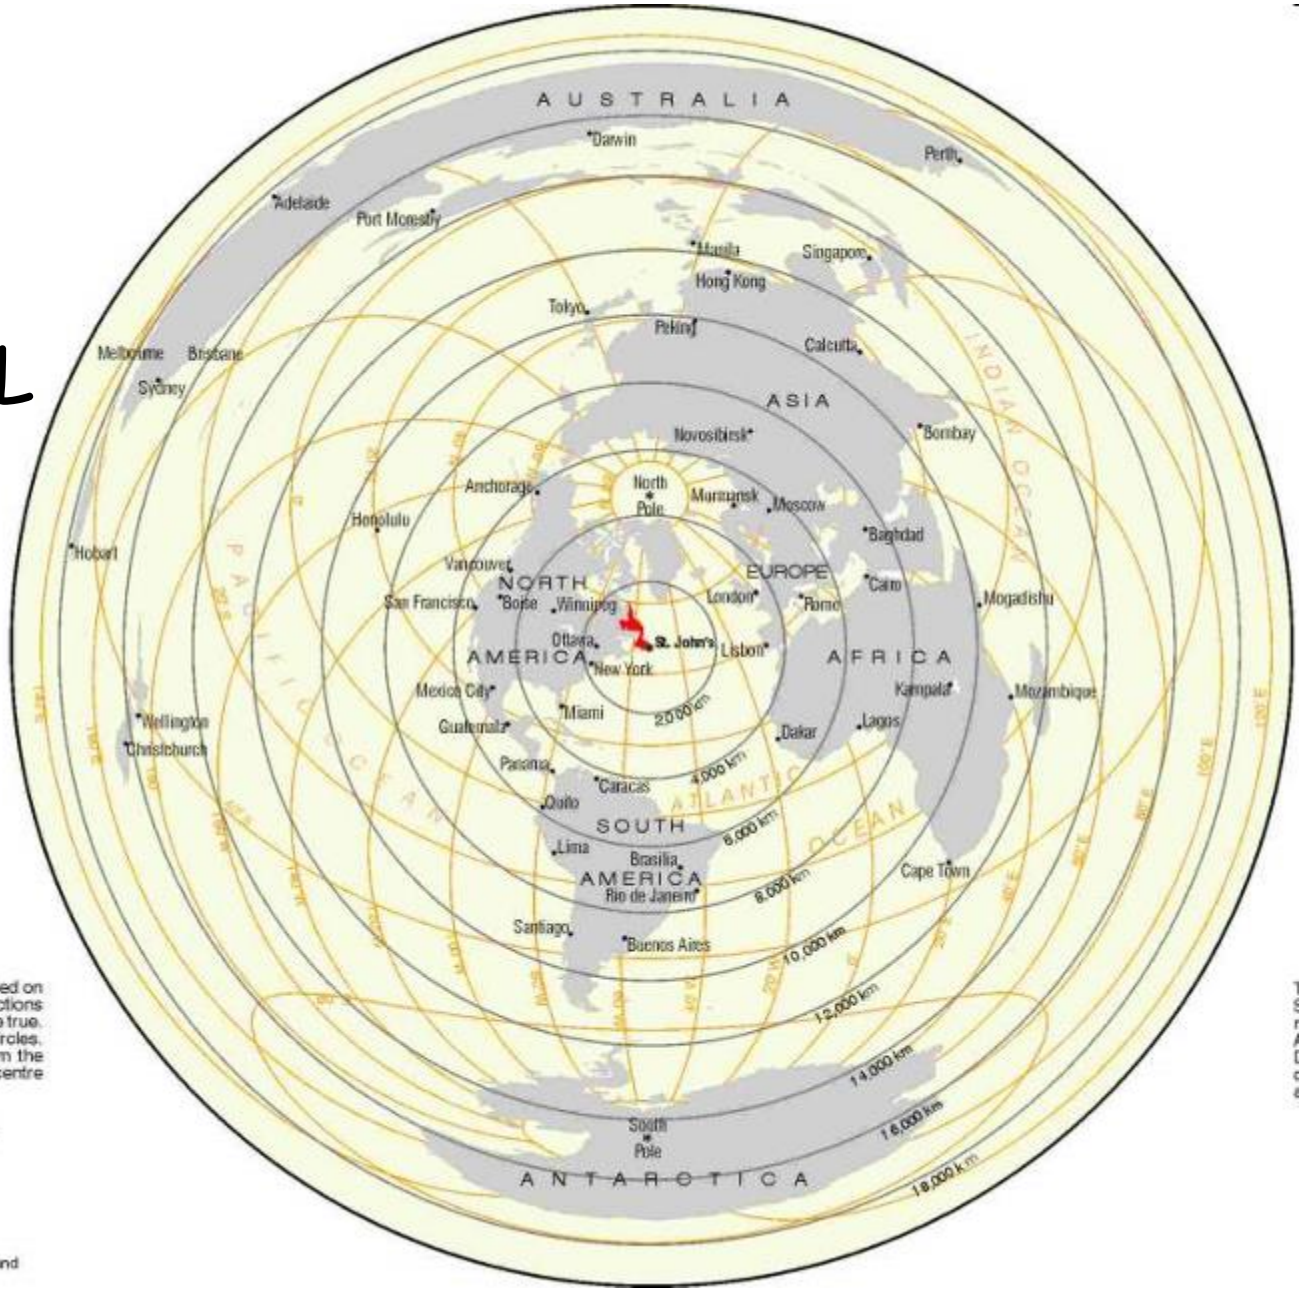
Like Earth, longitude zero is arbitrary – a feature is chosen

The Prime Meridian of the Moon lies directly in the middle of the face of the moon visible from Earth.



Azimuthal equidistant

centred on
St. John's, NL



This is an AZIMUTHAL EQUIDISTANT PROJECTION centred on St. John's, Newfoundland. Only distances and directions measured along straight lines radiating from the centre are true. All straight lines passing through St. John's are great circles. Deformation of the earth surface increases outward from the centre and measurements taken other than through the centre are inaccurate.

SCALE along any straight line through the centre

1000 0 2000 4000
Kilometres

1000 0 1000 2000 3000 4000
Miles

II. Cylindrical Projections 16th century

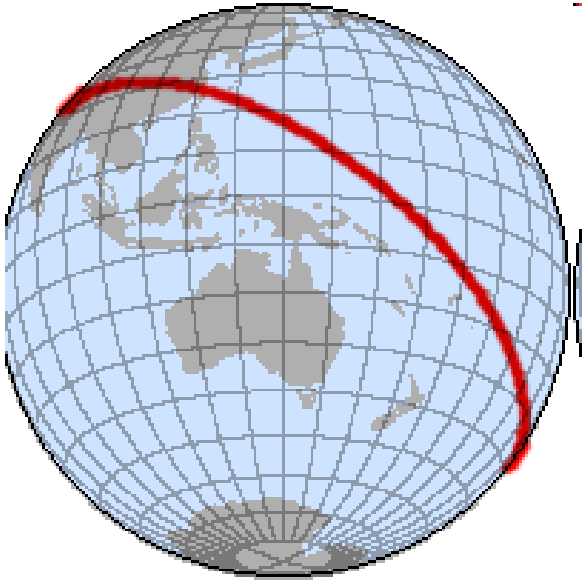
for early world maps
-They fill a rectangular shape

Plate Carrée

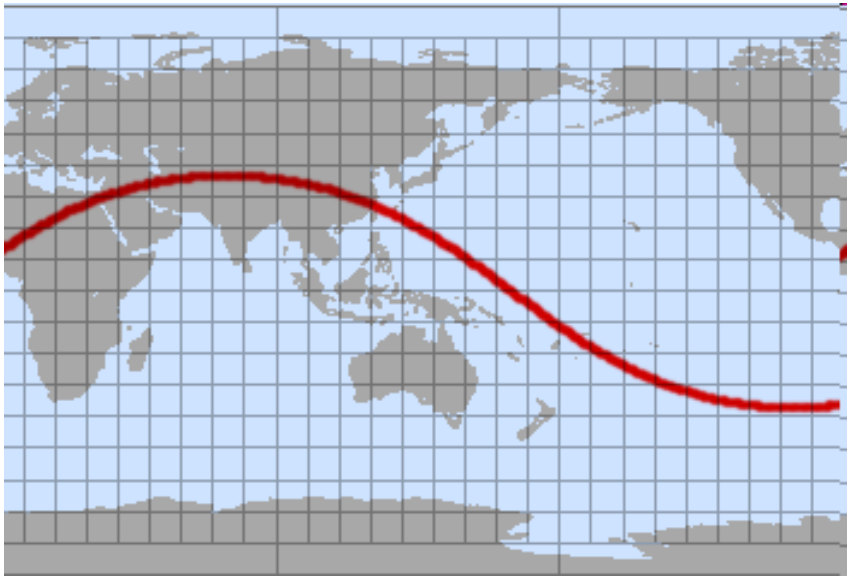
'Great circles' are straight lines in 3D space

e.g. meridians, equator, flight lines … but not any other parallels

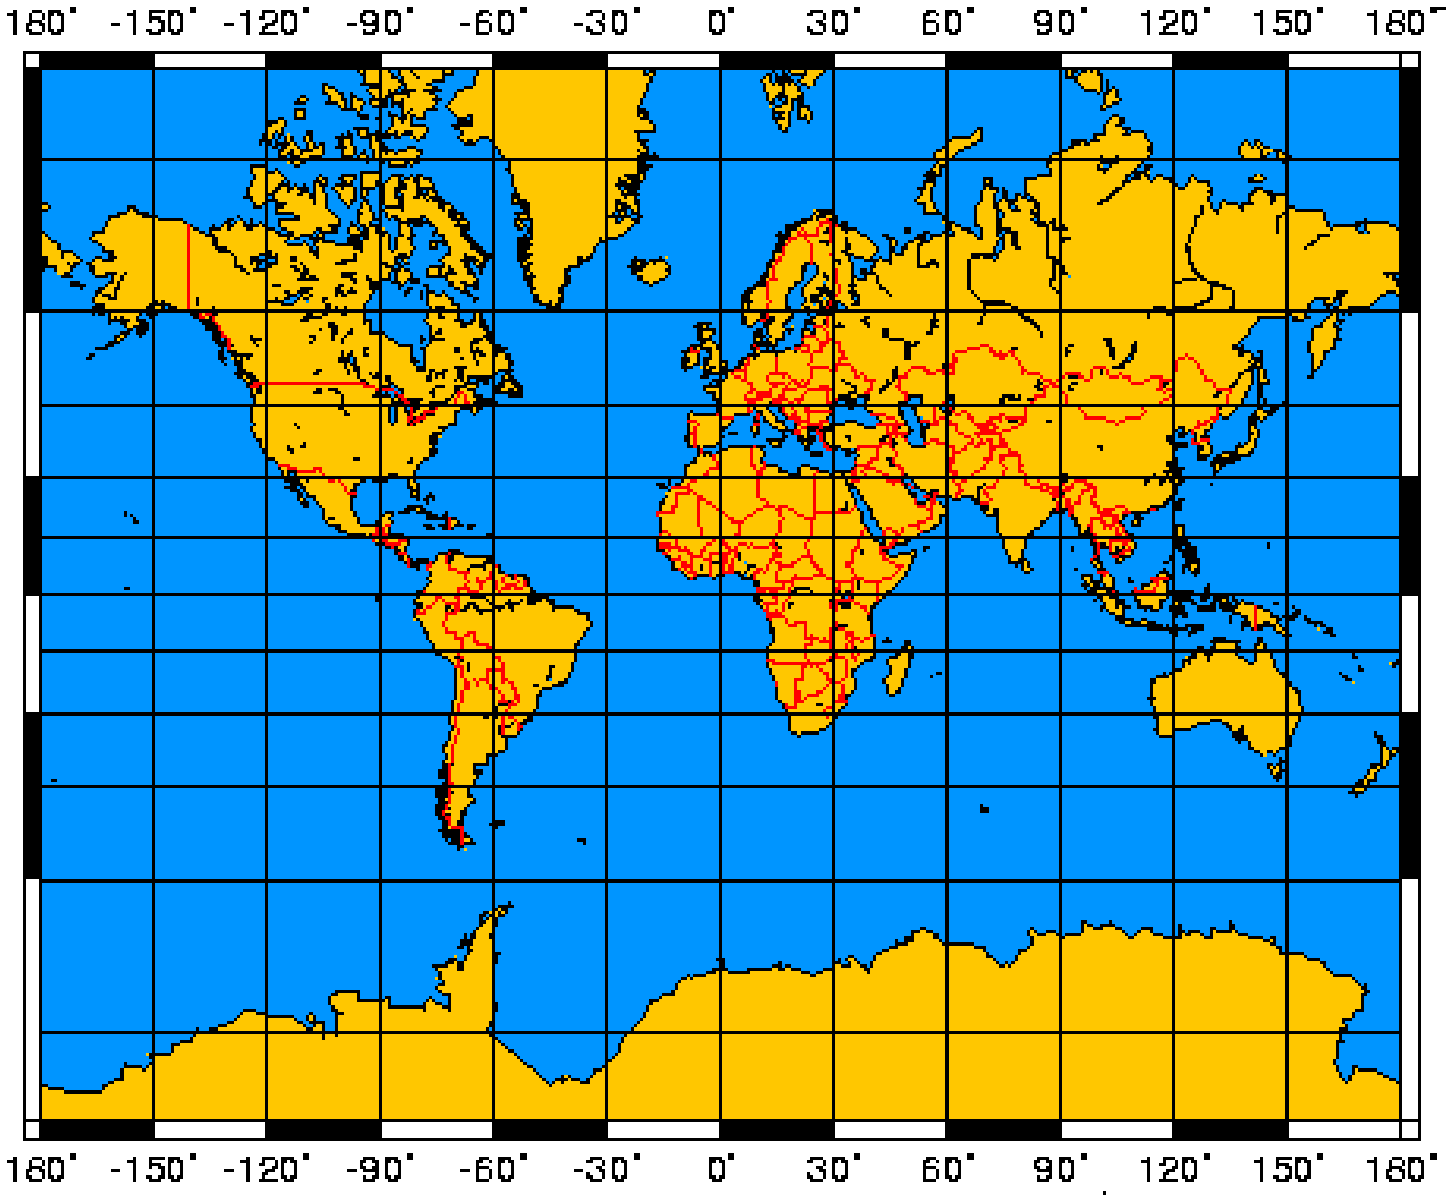
Of all projections, only the **gnomonic** retains all great circles as straight lines



e.g. Equidistant rectangular projection



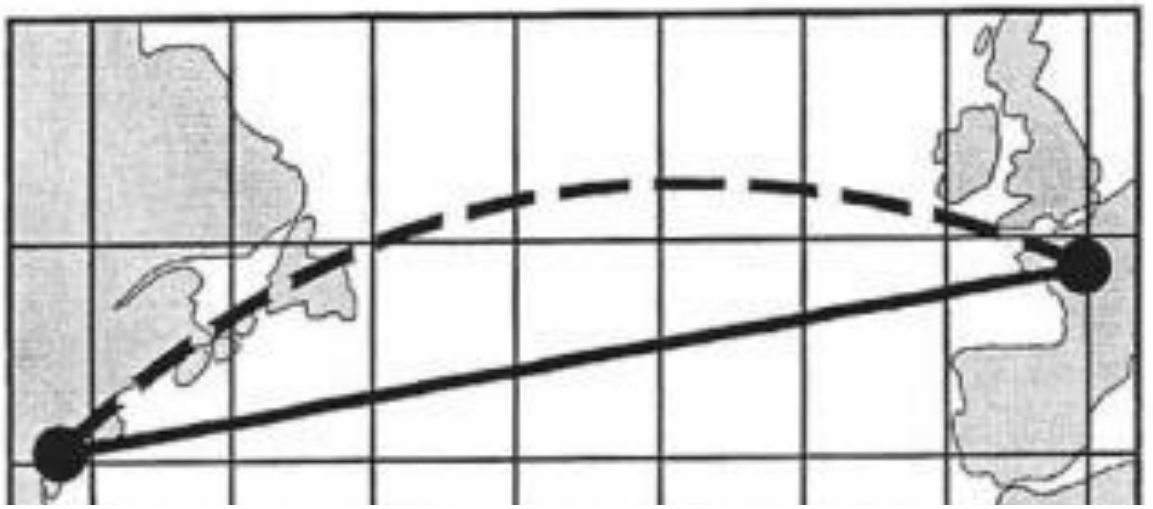
Mercator's Projection 1569 - conformal = shape-preserving



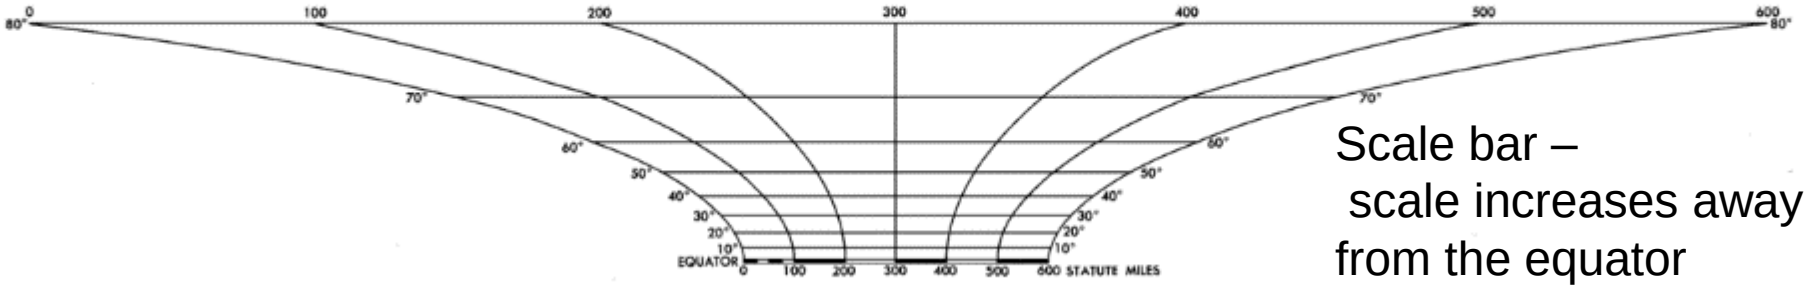
All 'straight lines' have constant compass bearings

= **Rhumb lines** (but the dashed line is the shortest route)

It became known as the "Navigator's friend"

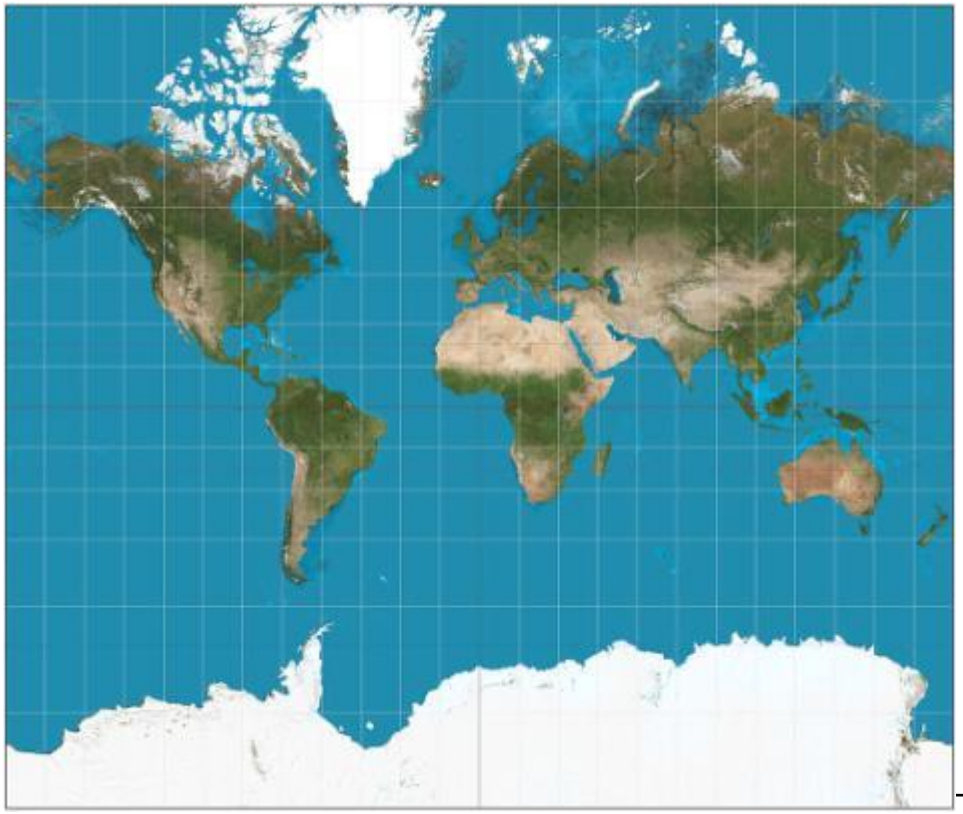


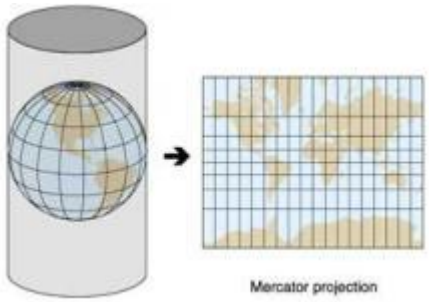
MERCATOR PROJECTION
Scale 1:14,000,000
One Inch = 221 Statute Miles at the Equator



Scale bar –
scale increases away from the equator

Mercator (1569) 'normal'

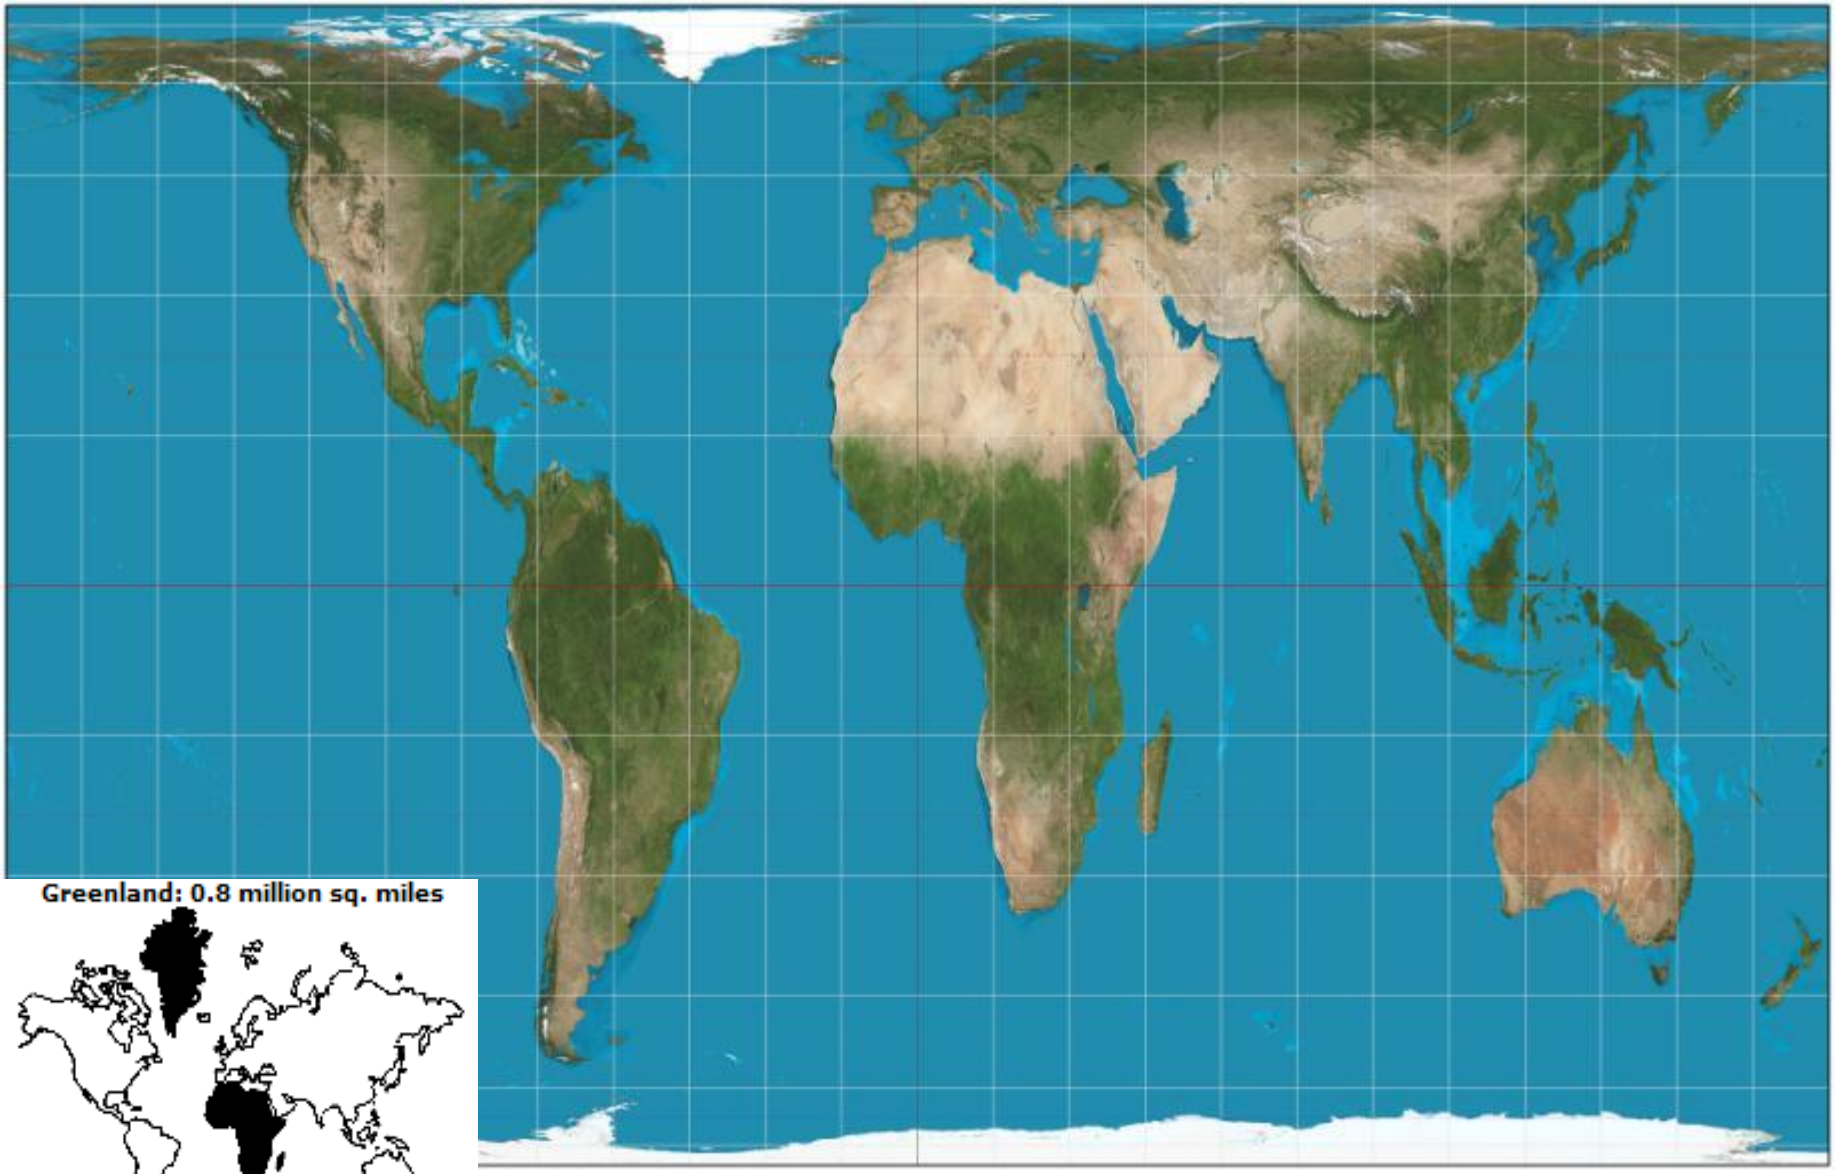




Transverse Mercator (1772)

The TM projection is the basis for the (Universal) UTM system
- Adopted by Canada post WWII,
- SYSTEM of 60 TM projections

(1885) Gall-Peters projection (1972) – equal-area



Corrects for area distortion, but note the impact on shape

III. Conic projections – 18th century

The cone opens along a line of longitude

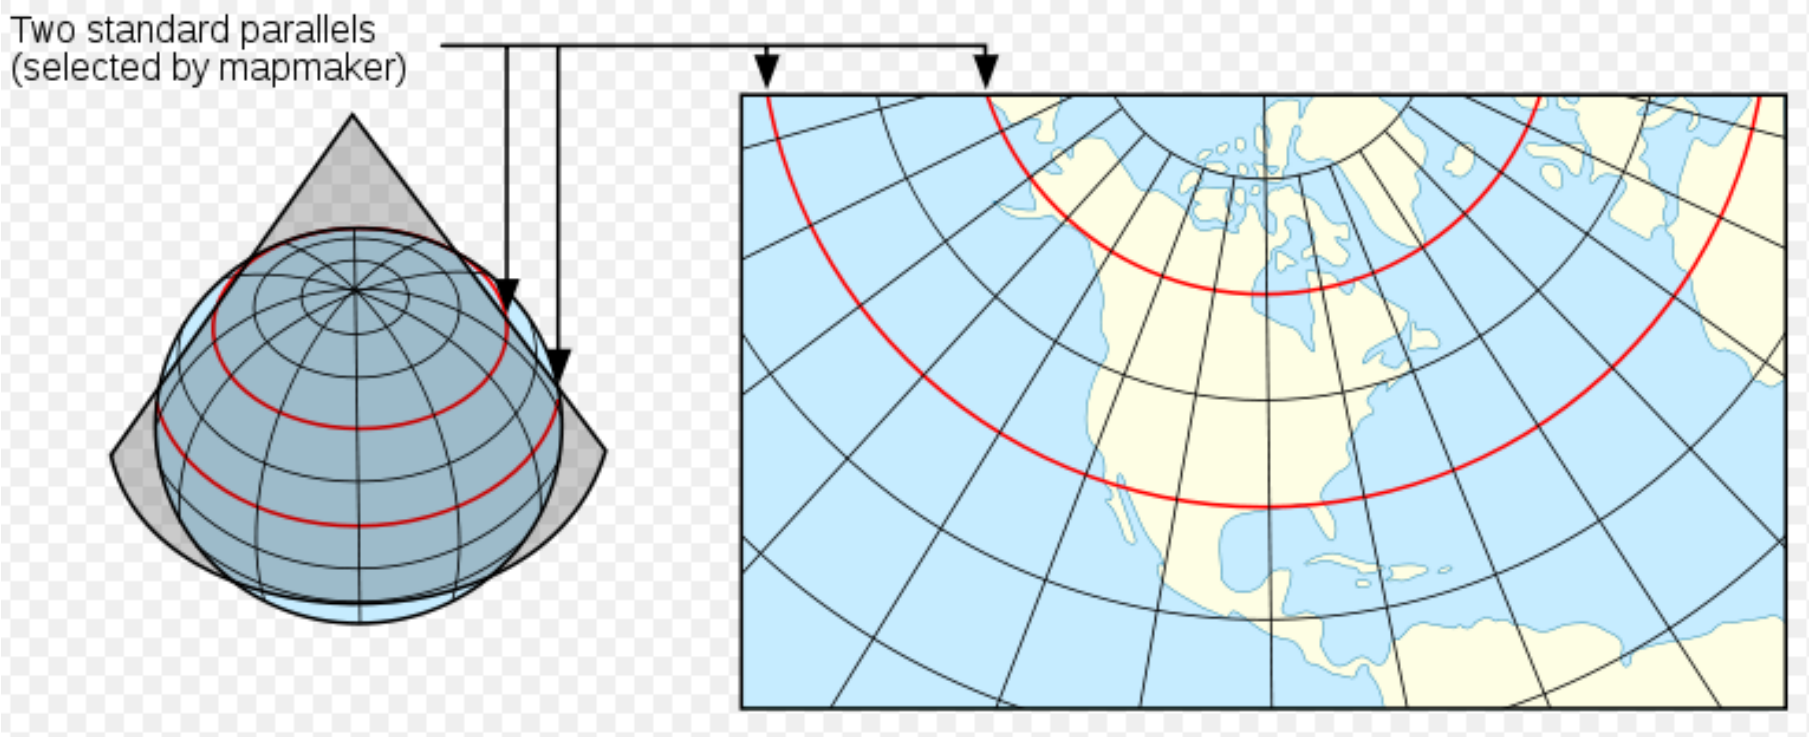
CONIC projections
(e.g. Albers)

… are all 'normal orientation'

They can be varied by :

A: angle of the cone

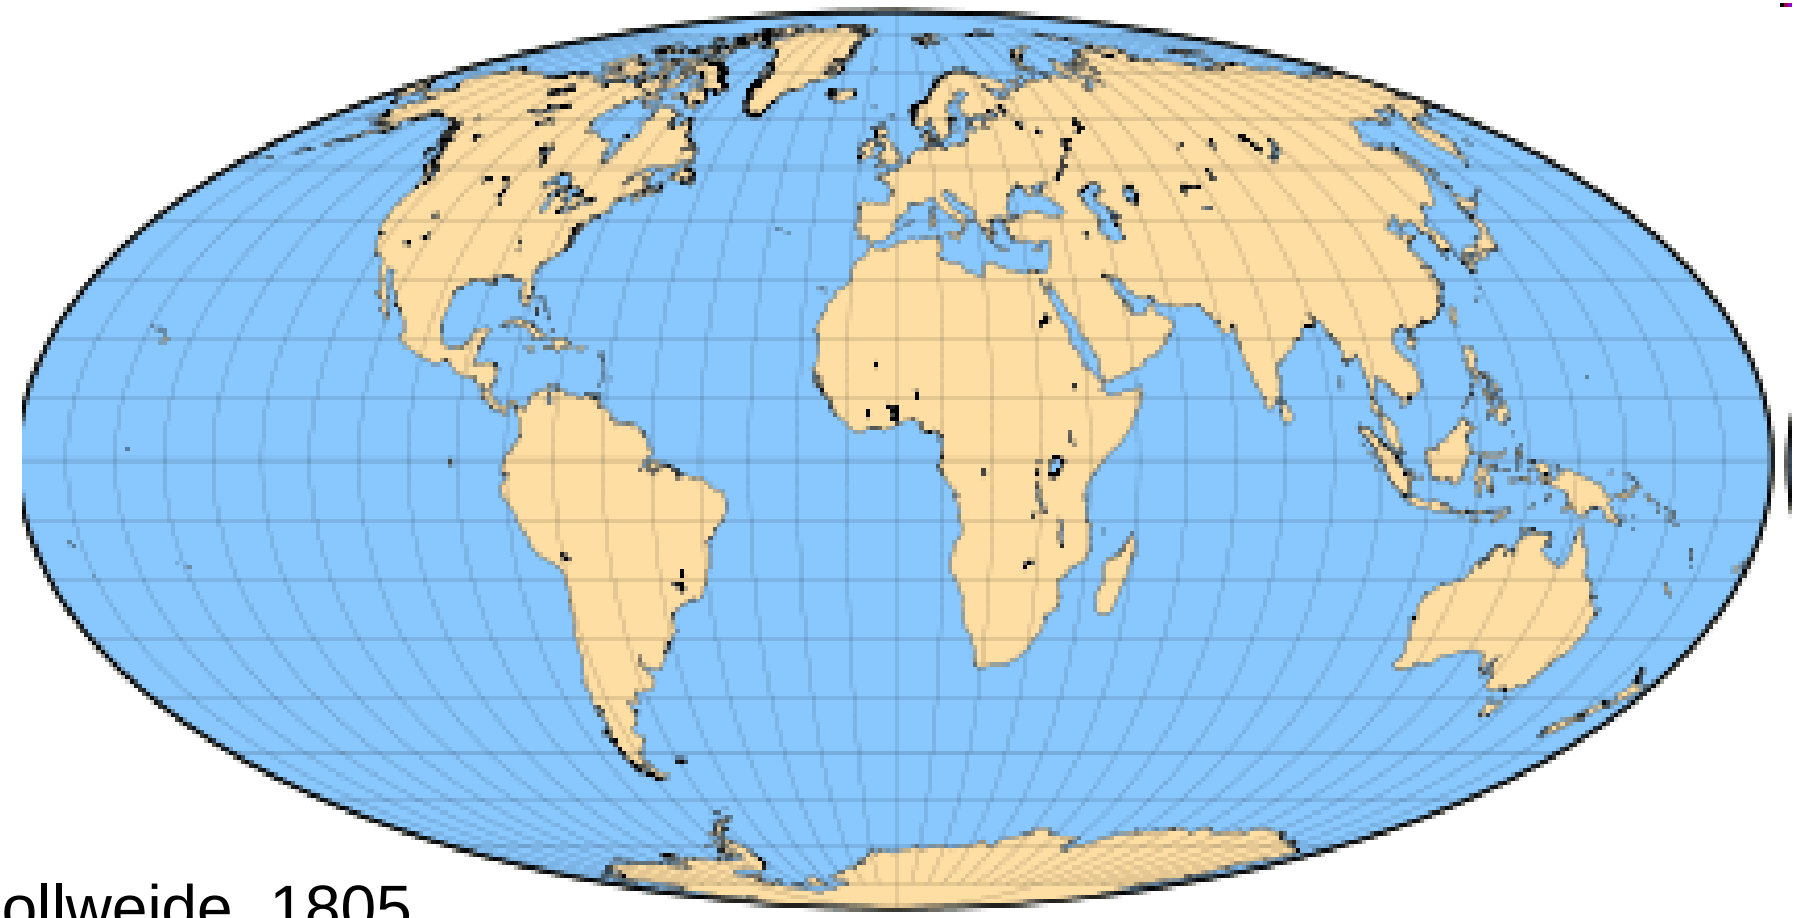
B: 1 or 2 standard lines



IV. Pseudo-cylindrical Projections

-19th century (and 20th)

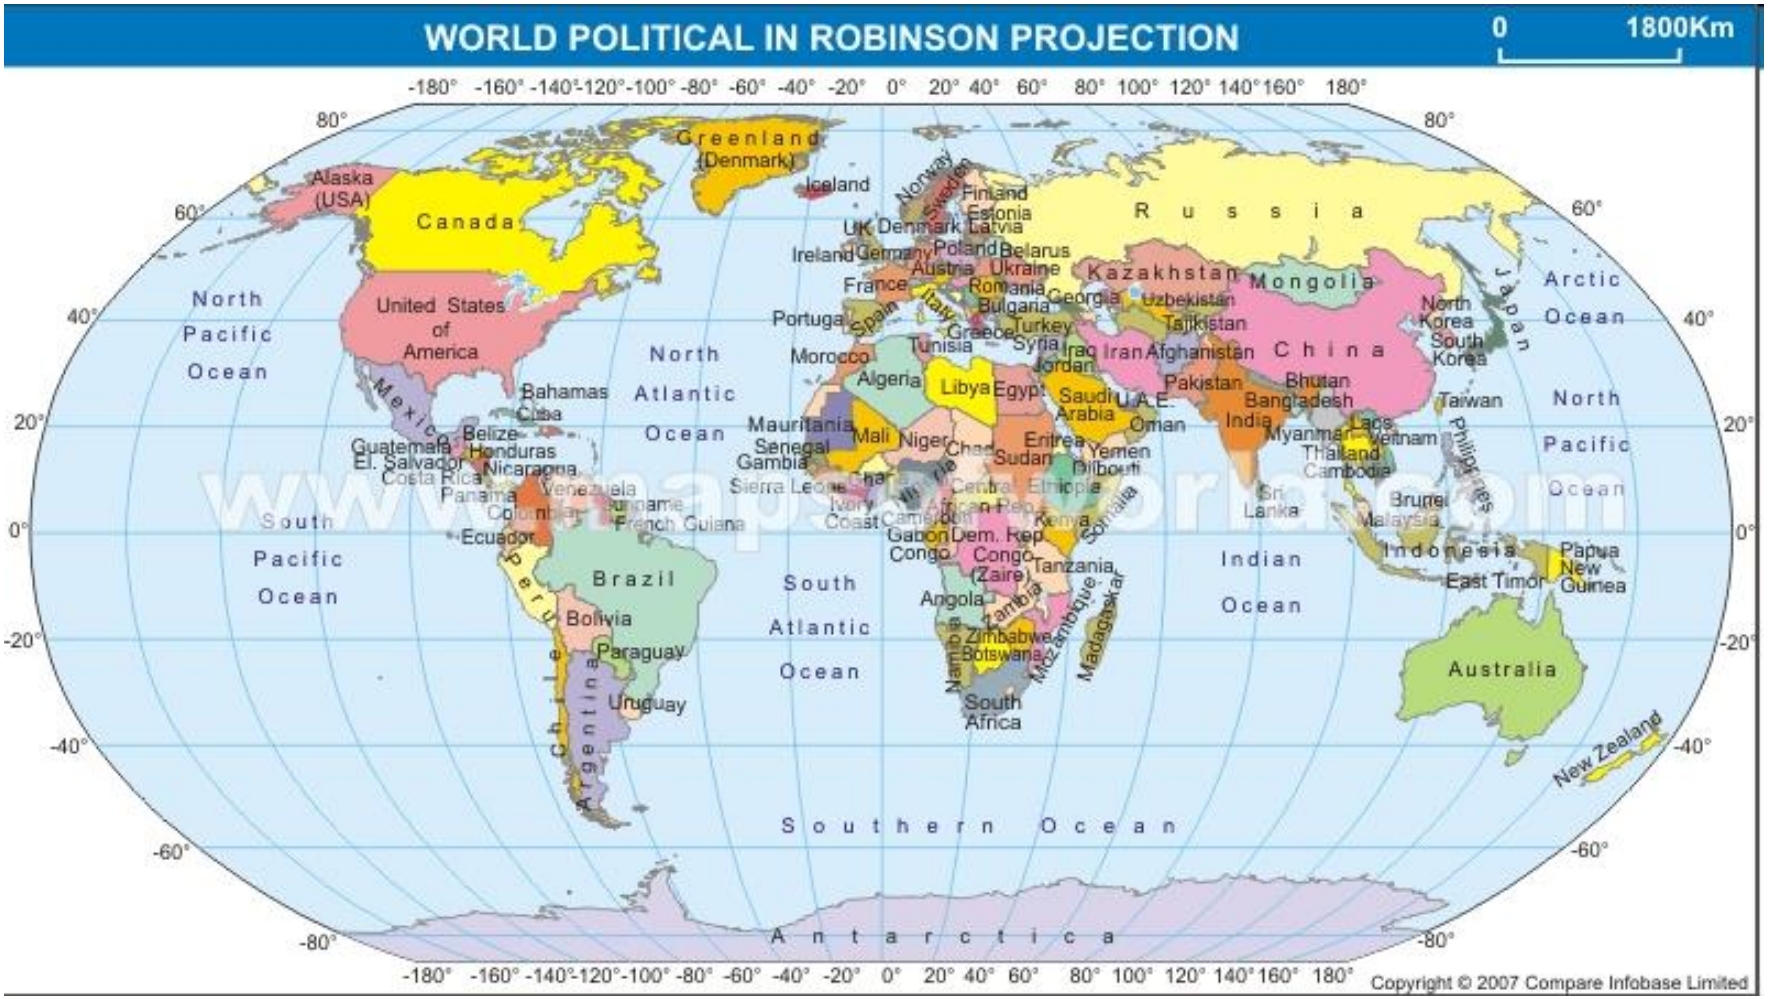
These are geometrically constructed. The parallels are generally equally spaced but are made more proportional to their real length to minimize distortion.



Mollweide, 1805

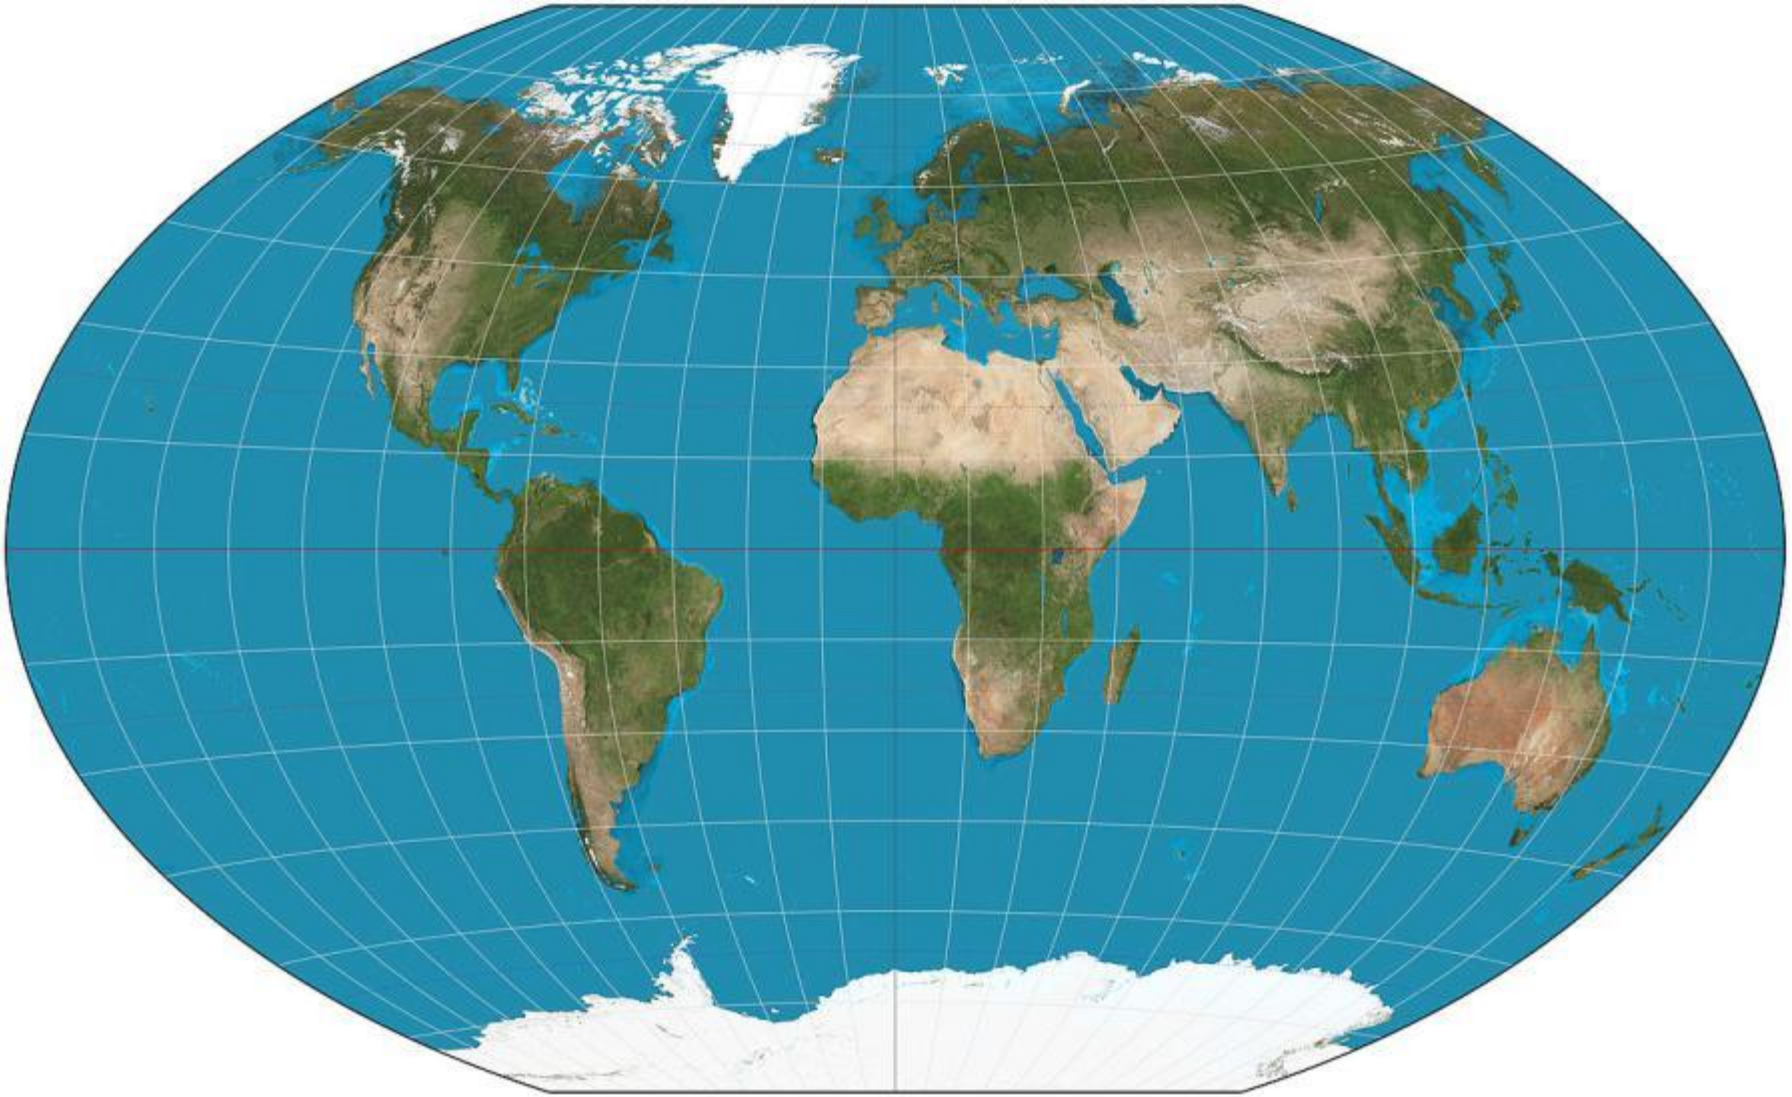
Robinson projection (1963) adopted by National Geographic 1988

Poles drawn as lines to create better shapes



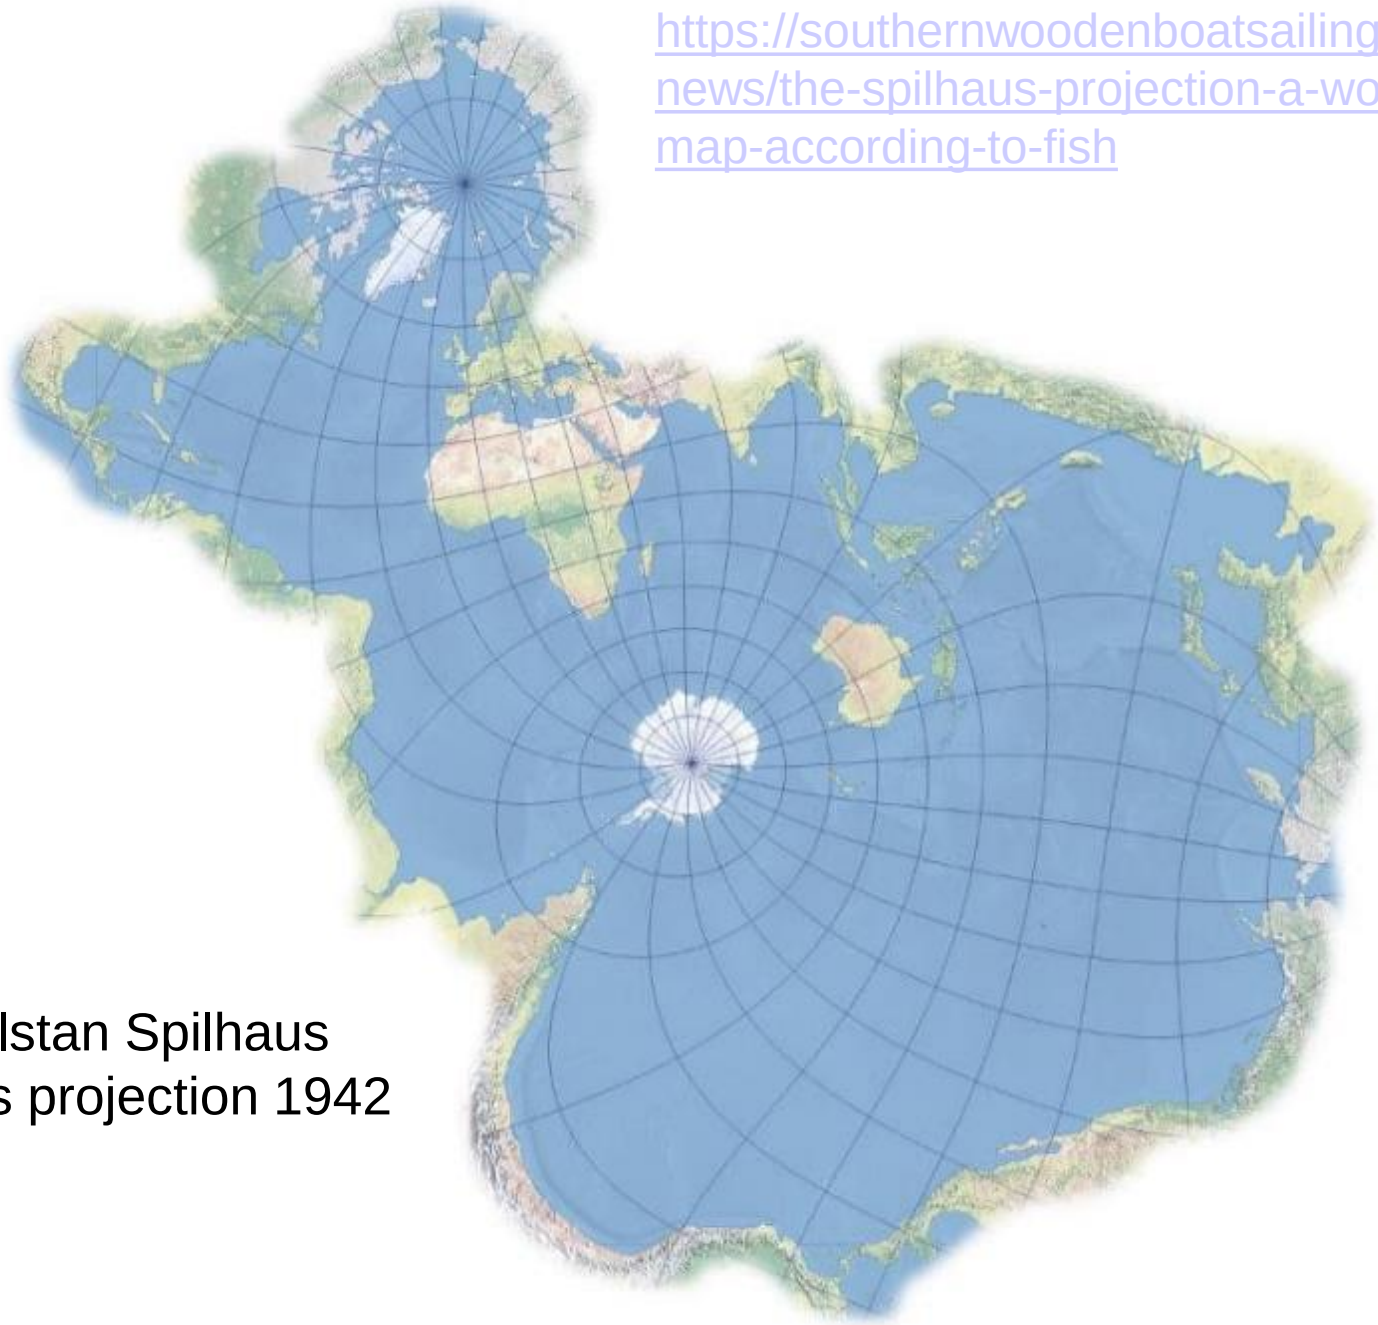
http://www.mapsofworld.com/projection-maps/robinson/world-political-light.html

The **Winkel tripel (Winkel III)** by Oswald Winkel in 1921, adopted by NatGeo in 1998. The name *Tripel* refers to Winkel's goal of minimizing three kinds of distortion: area, direction (shape), and distance.



IVa. Interrupted pseudo-cylindrical (e.g. Goode's, 1923)

https://southernwoodenboatsailing.com/news/the-spilhaus-projection-a-world-map-according-to-fish



Dr. Athelstan Spilhaus
Spilhaus projection 1942
