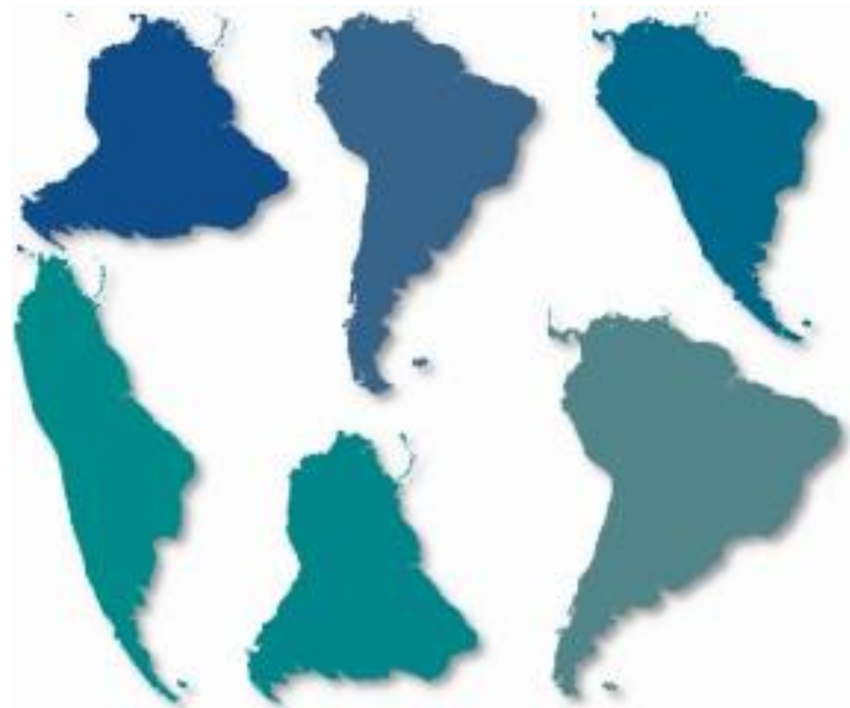
Map projections 1: principles

How can we 'project' a 3D globe onto a 2D display?

..only a globe maintains all spatial qualities without distortion

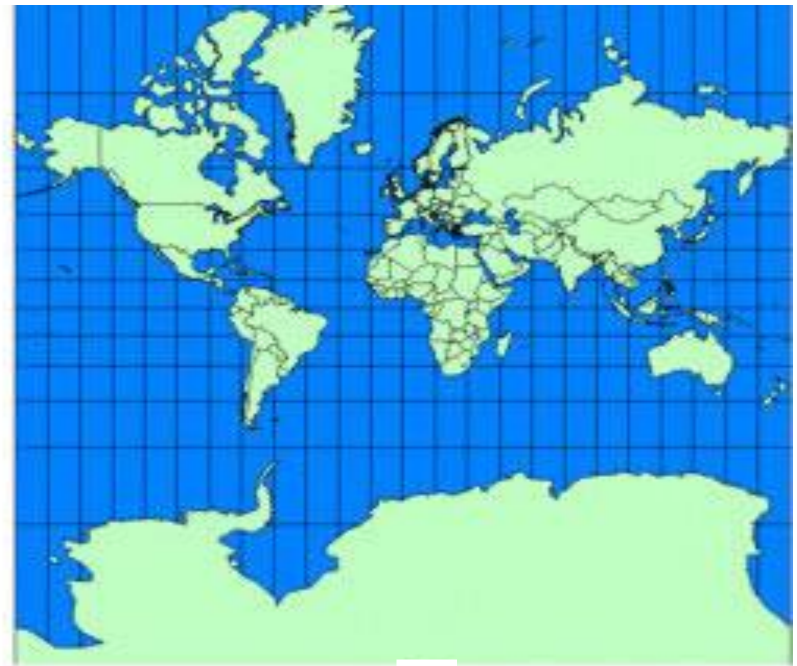


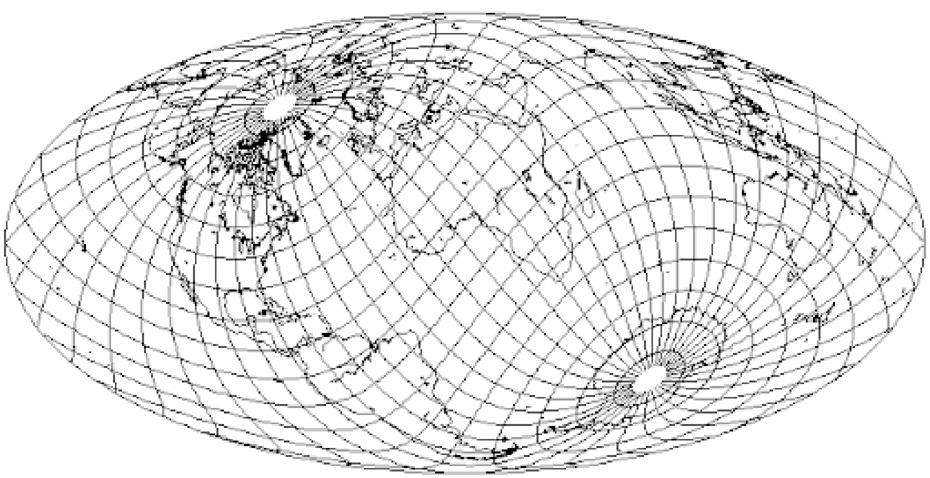
https://imgur.com/t/science_and_tech/53iqEMC

What is a Map Projection?

mathematical expression showing the 3D surface on a 2D map

This process always results in distortion

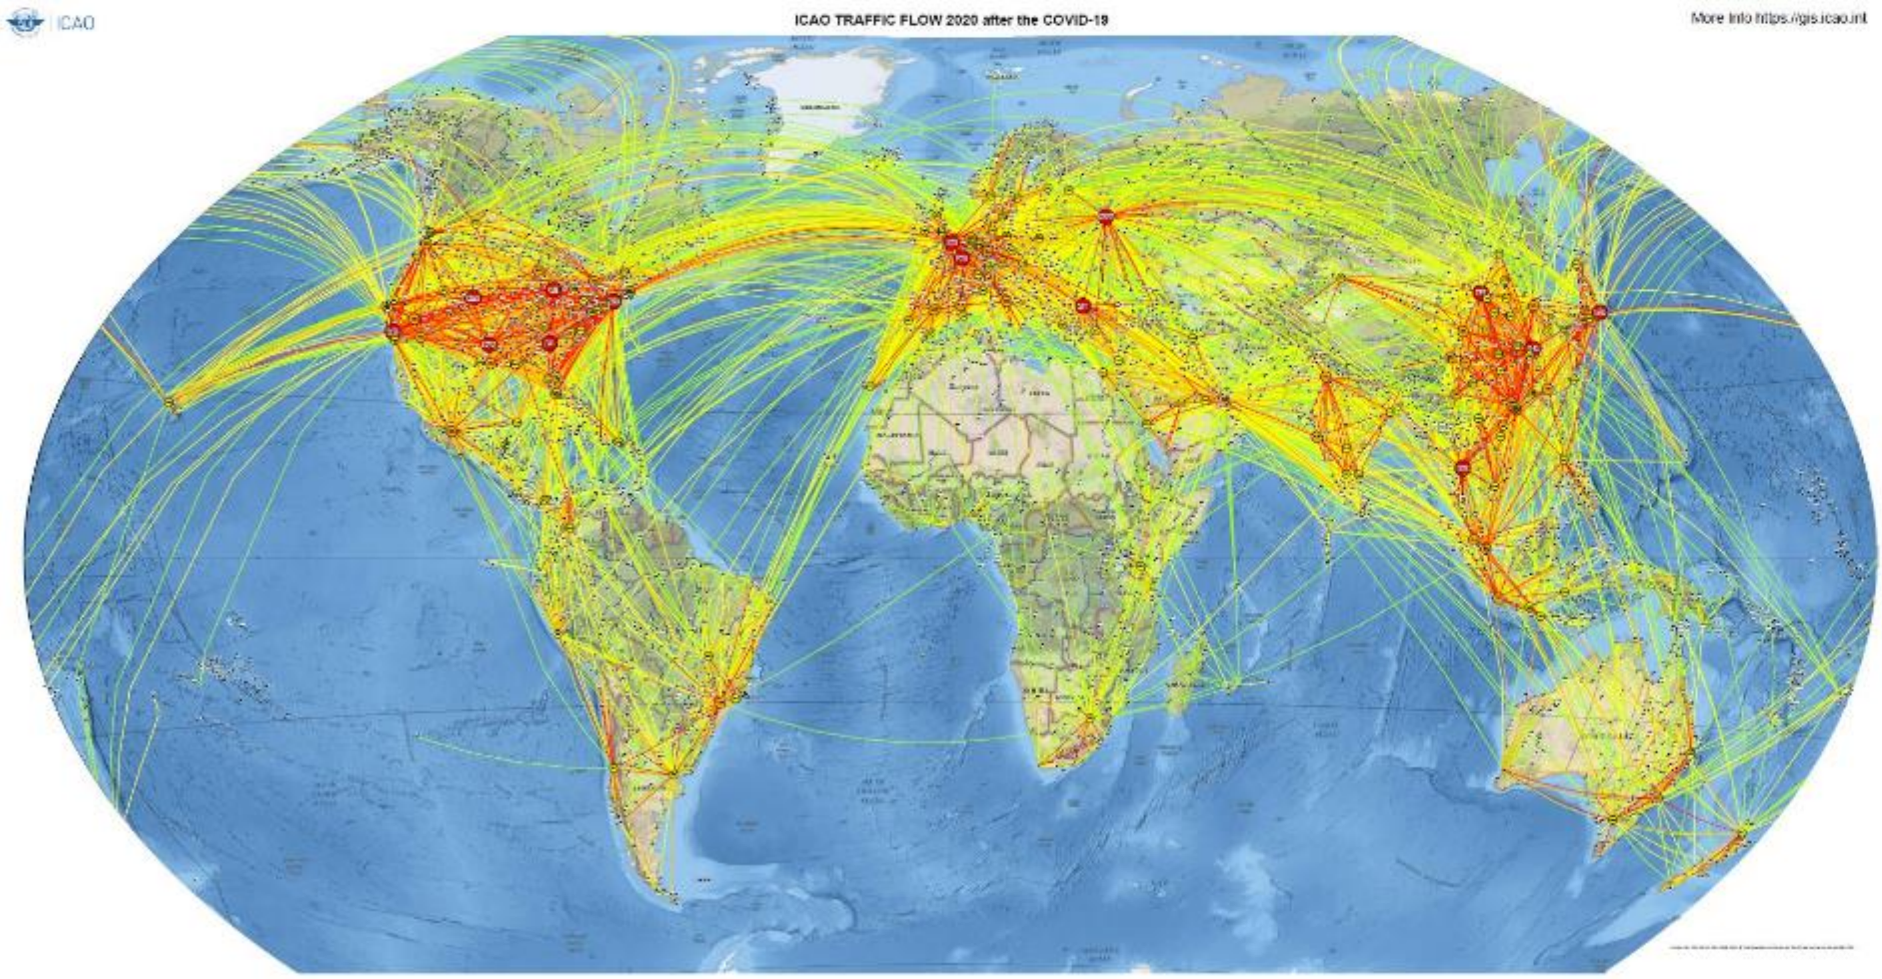




Mercator projection (shape)

Oblique Mollweide (area)

Why don't planes fly on straight lines – well they do …

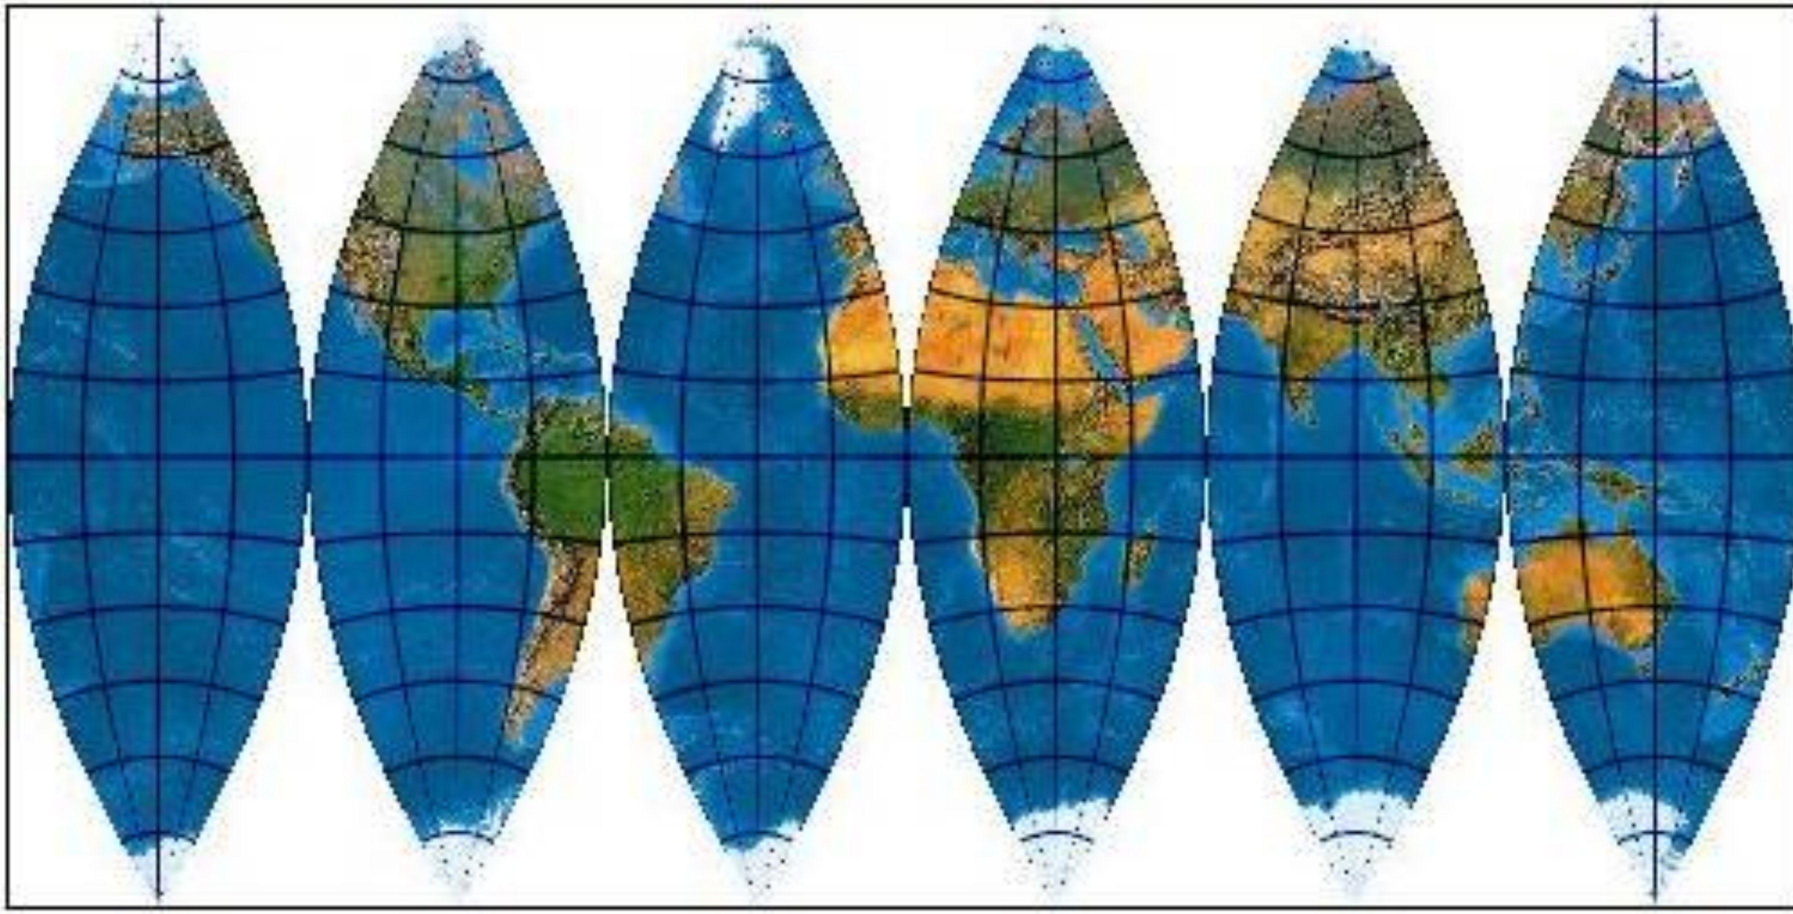


flight routes are 'great circles' … straight line in 3D space – but curves here

The world could be mapped like bit of orange peel …

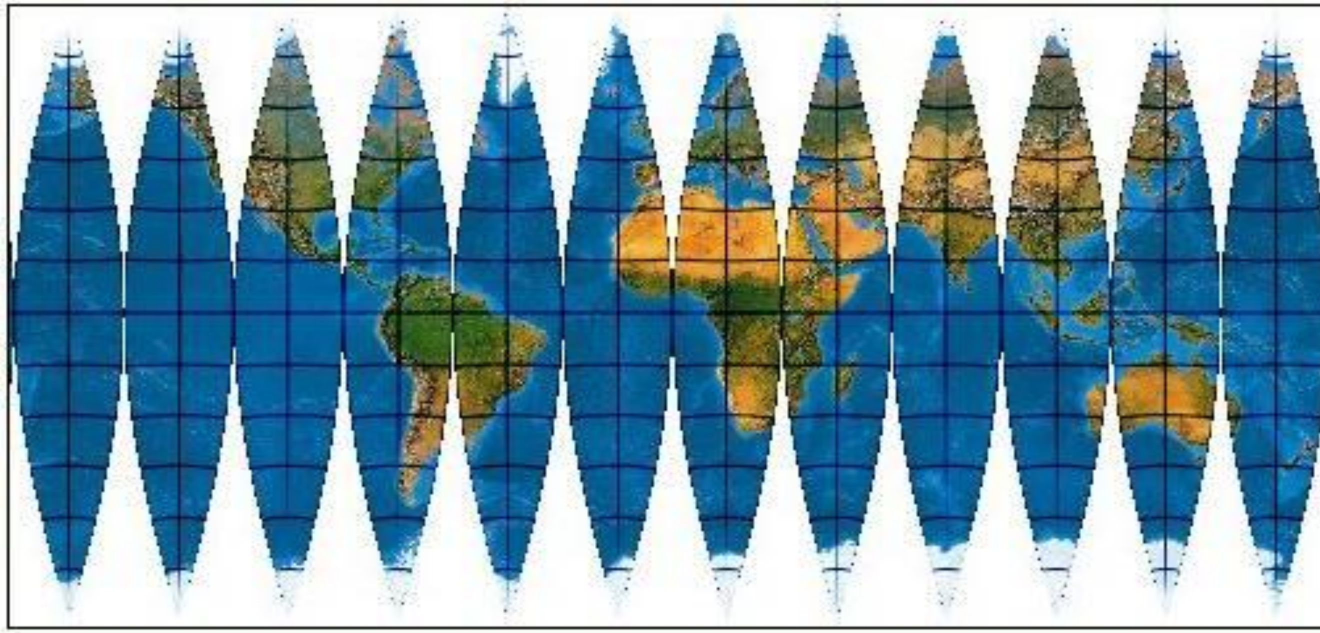
- maybe not a problem locally, but it is for large areas

the strips would still have some curvature
.. and gaps between the strips



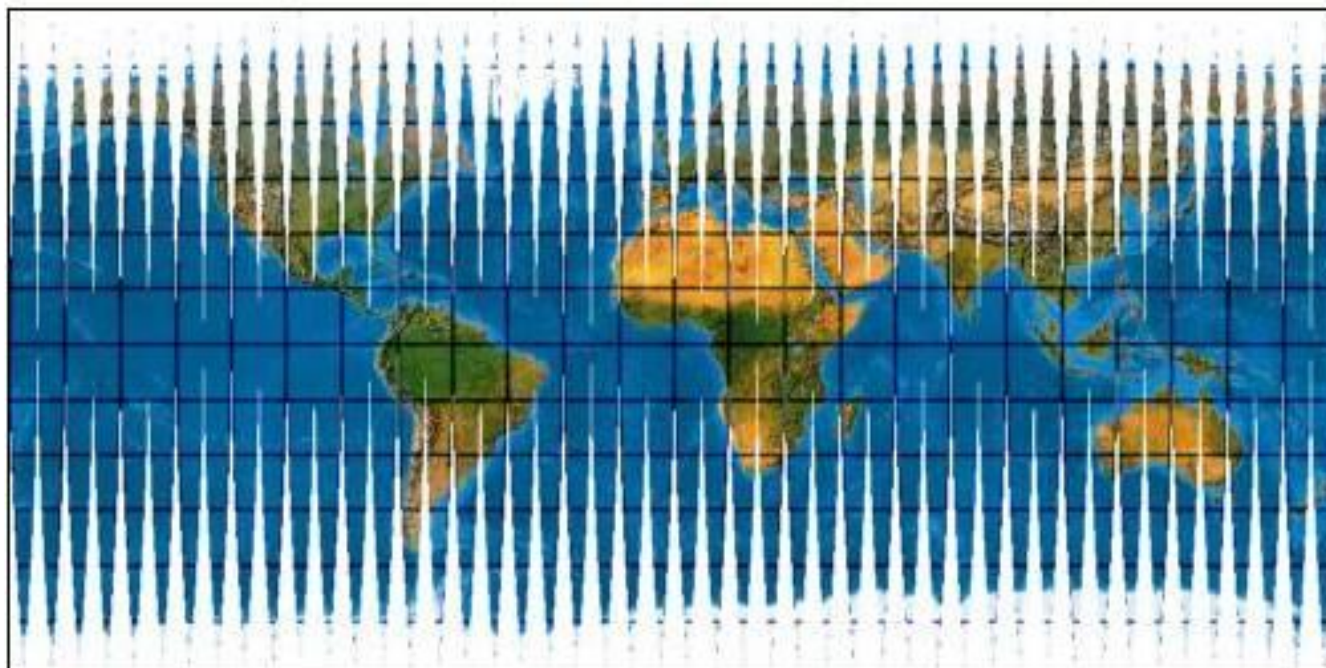
http://boehmwanderkarten.de/kartographie/is_netze_globussegmente.html

12 pieces



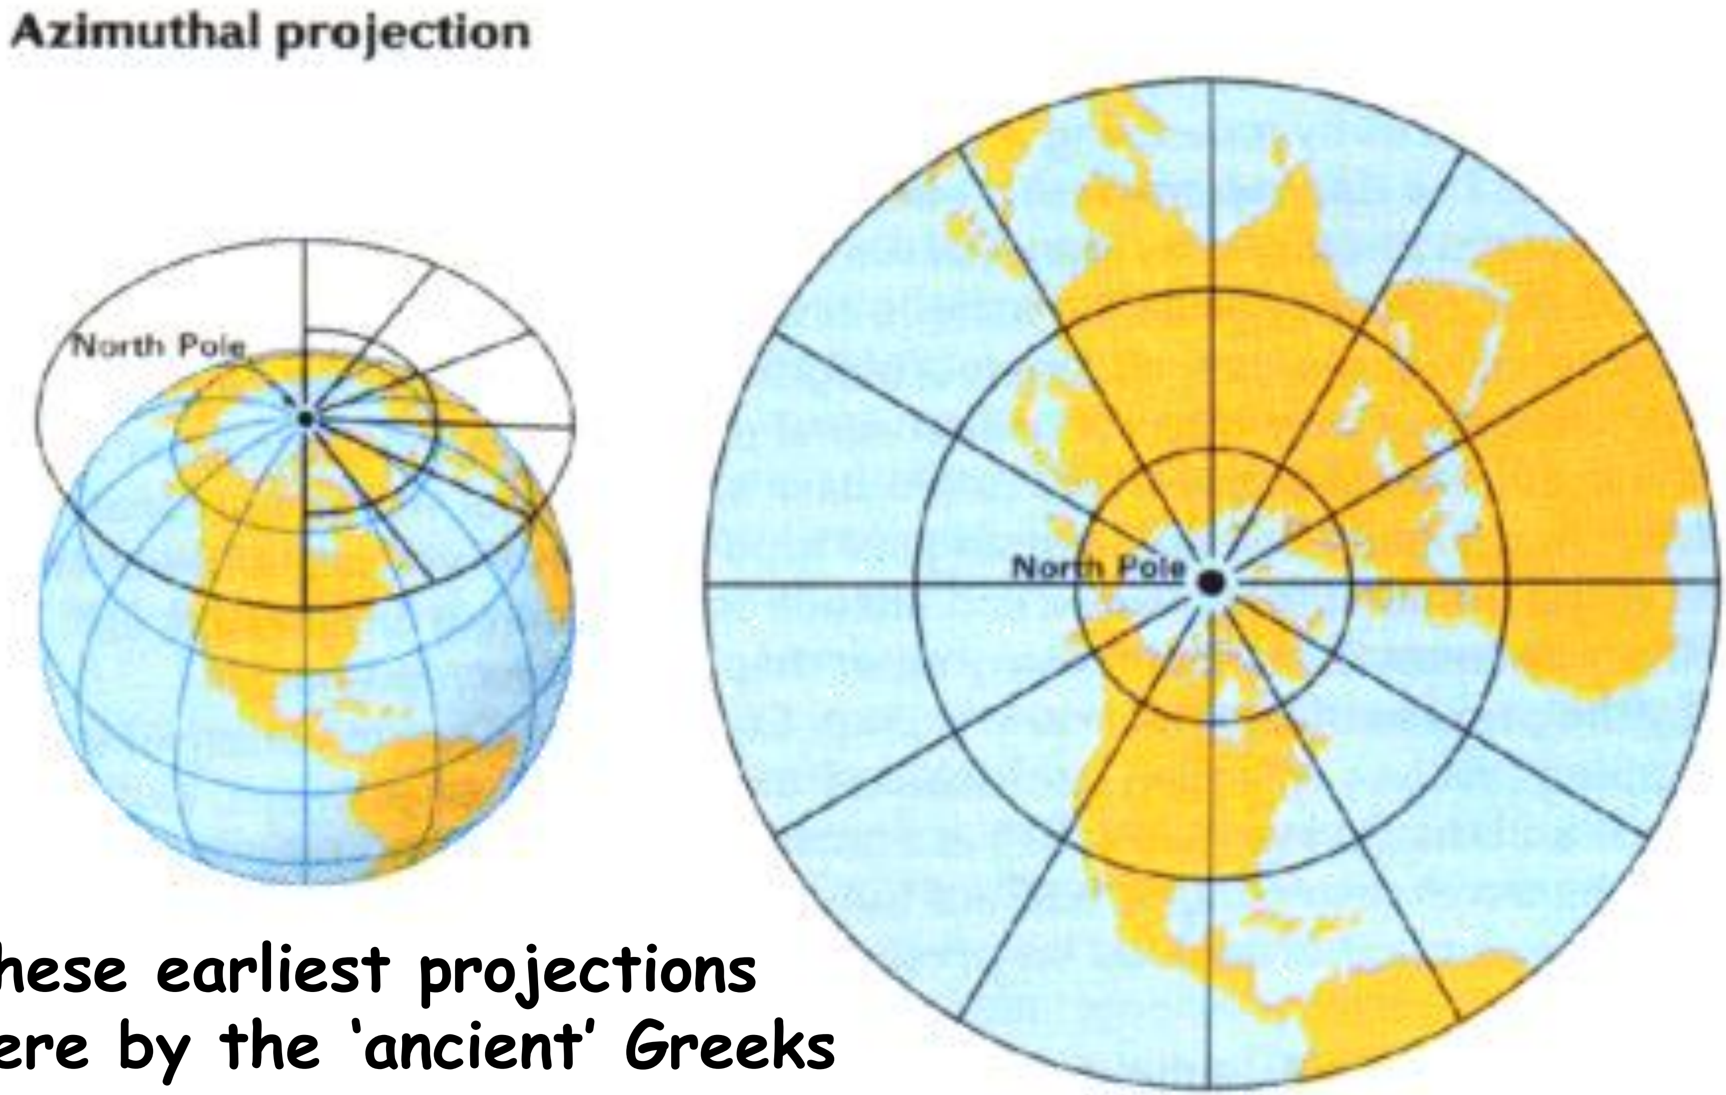
48 pieces

becoming like
UTM zones..



Or they can be made by literally 'projecting' the globe onto a map …

Azimuthal (planar) projections



These earliest projections were by the 'ancient' Greeks

Projection Terms

1. Scale Factor (SF)

SF = scale at any location /
divided by the 'principal scale'

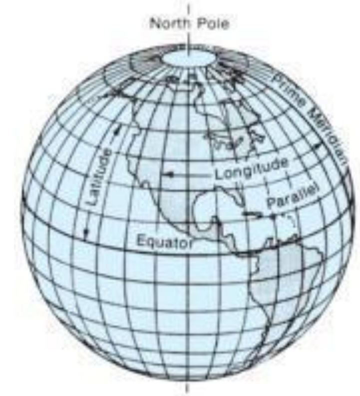
e.g. if scale = 1:2 million and principal scale = 1:1 million

then SF at that point = ½ million divided by 1/1 million
= 1/2 (0.5)

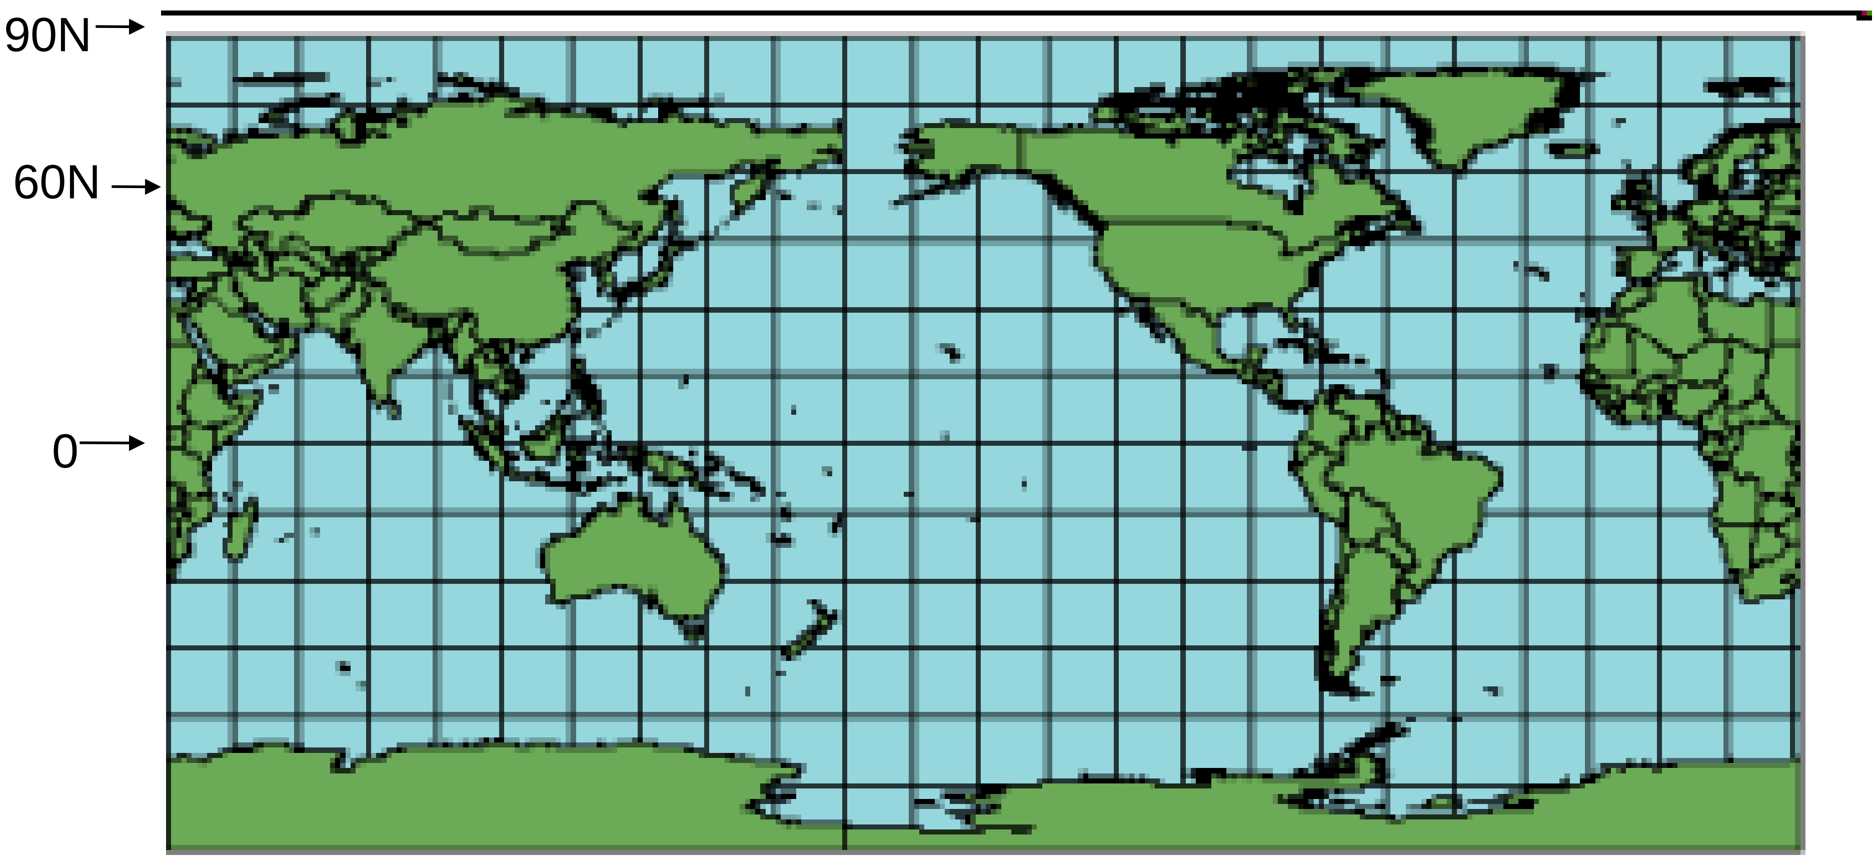
e.g. Canadian NTS maps: 'scale factor 0.9996 at UTM zone edge'

The Plate Carrée projection

e.g. where every line of latitude is equal in length



SF along lines of latitude are: equator SF = 1;
at 60°N/S, SF =2   at 90°, SF = ∞ or ‘undefined’



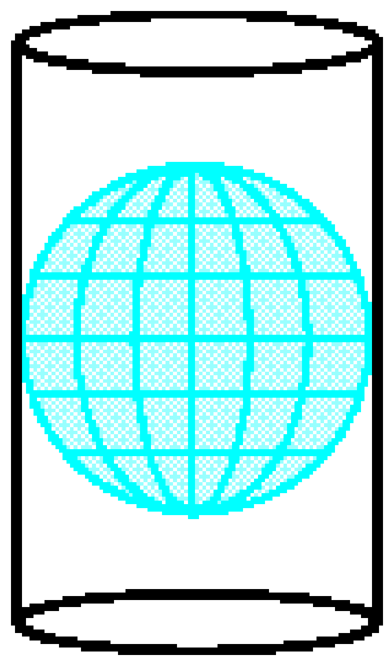
The SF in the other direction (along meridians) is 1

2. Developable surfaces:

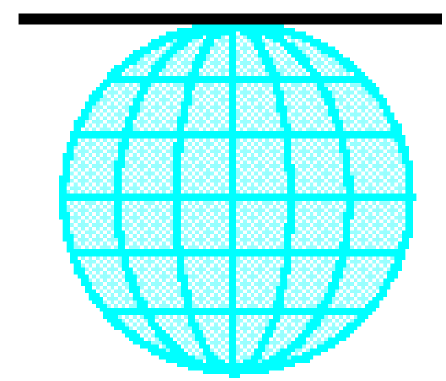
A two dimensional surface onto which the globe is projected

Conic

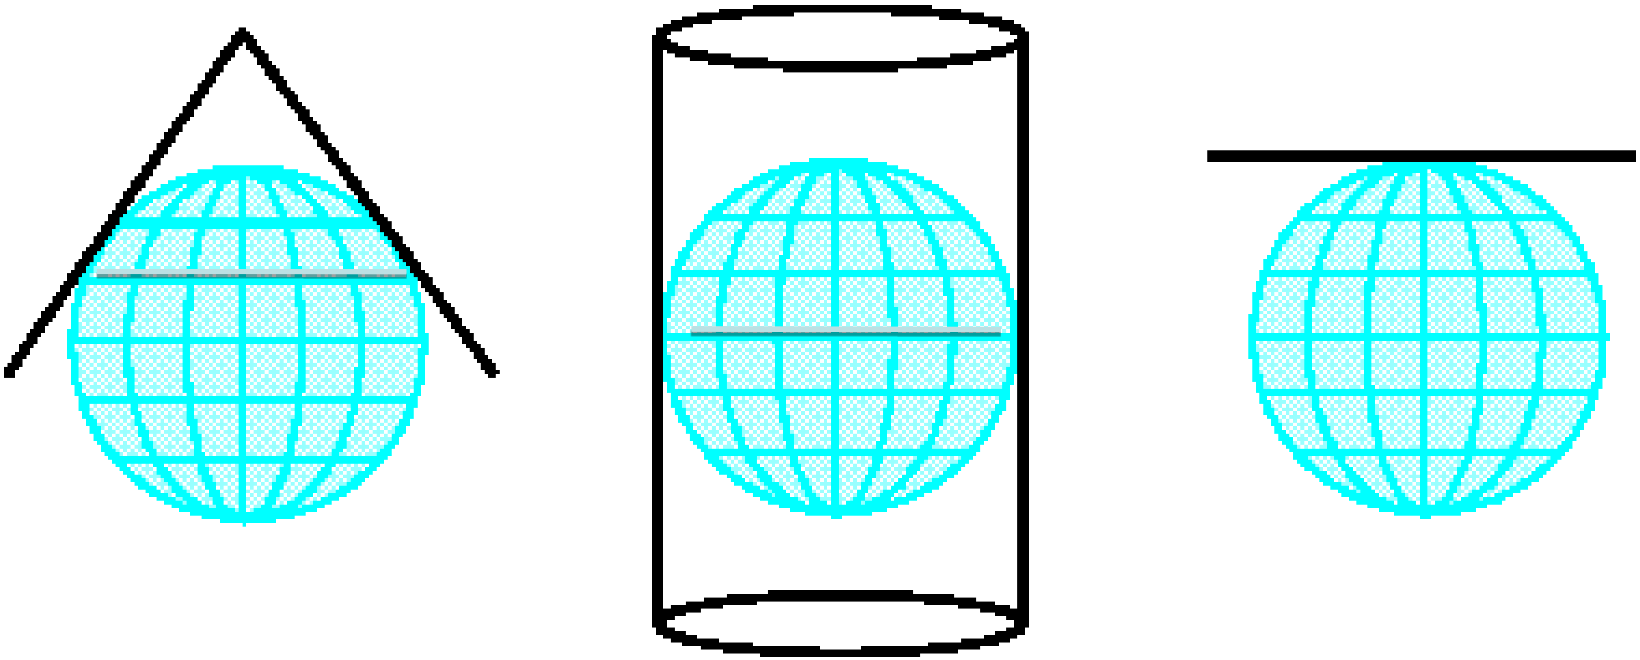
Cylindrical



Azimuthal (planar)



3. Standard Lines

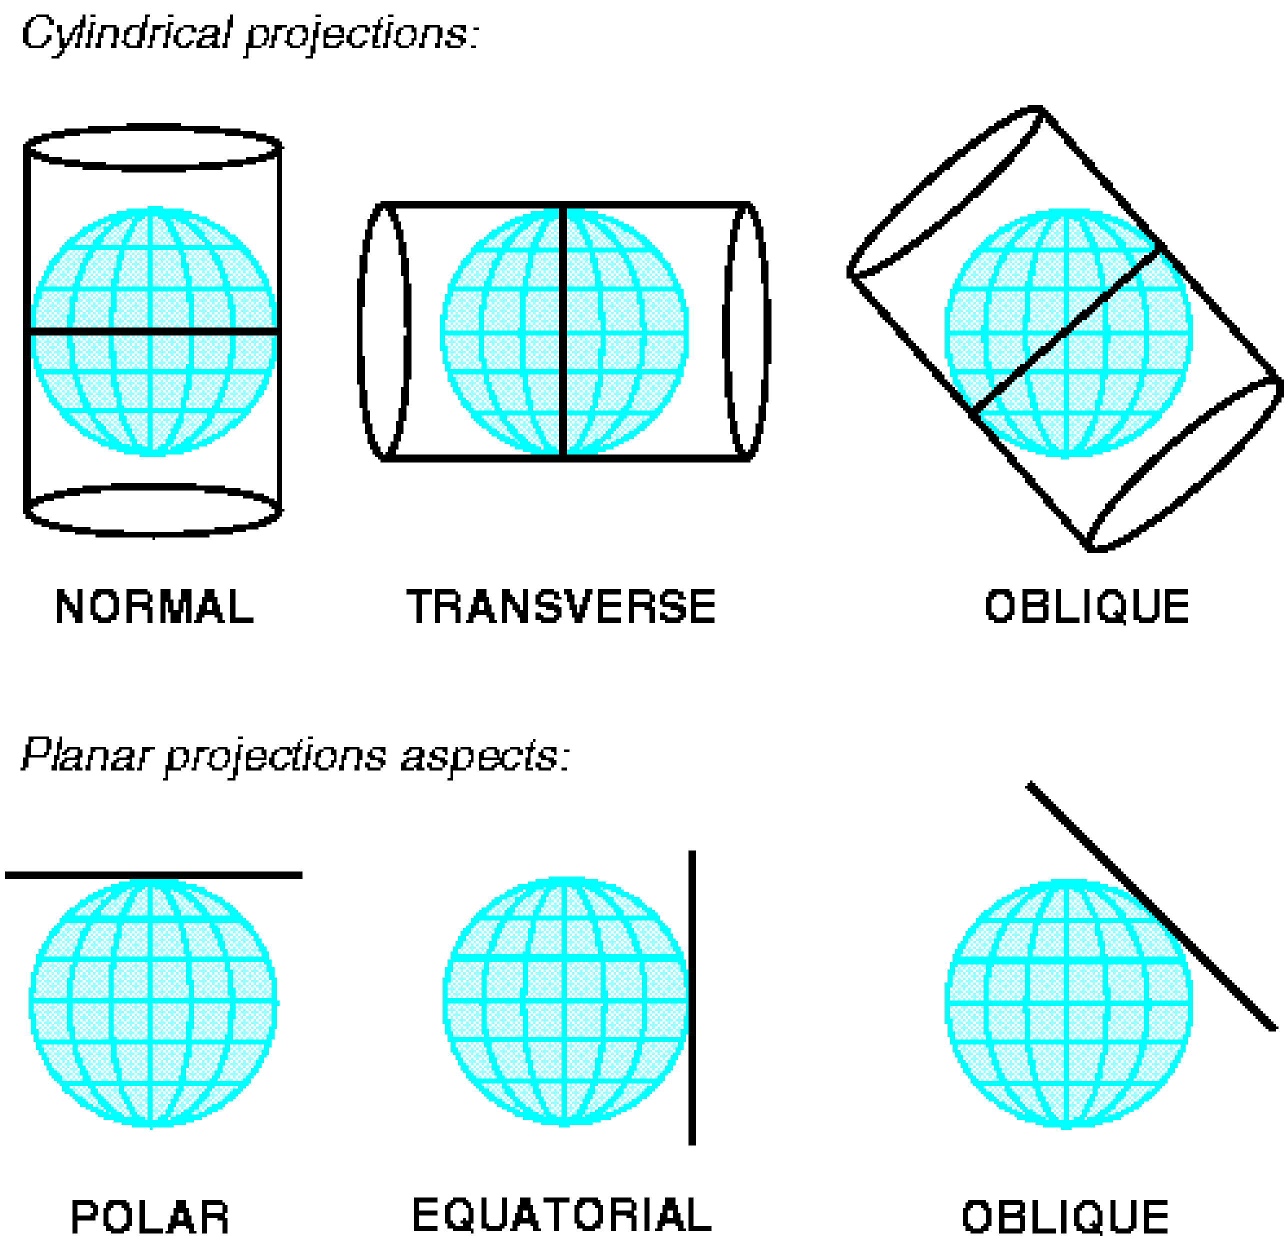


Distortion increases with distance between the 'globe' and the surface

The standard line has a scale factor = 1

(it is often the line of contact)

4. **Drawing of Projection Orientation**



5. Distortion: .... compare to the graticule:

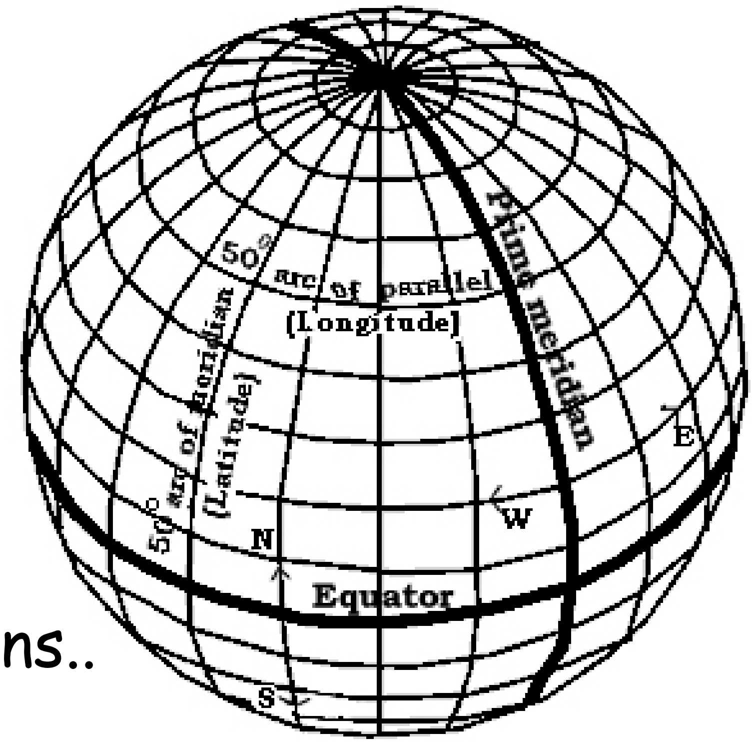
- Lines of latitude are 'parallel' and evenly spaced.

- Meridians converge at the poles,

 (half the distance at 60° N/S).

- Scale factor is 1 in all directions.

On the globe, but not any projections..



6. Projection properties

A projection can preserve

- **Shapes or**
- **Areas or**
- **Distances or directions (but not all)**

….. and never more than one of these

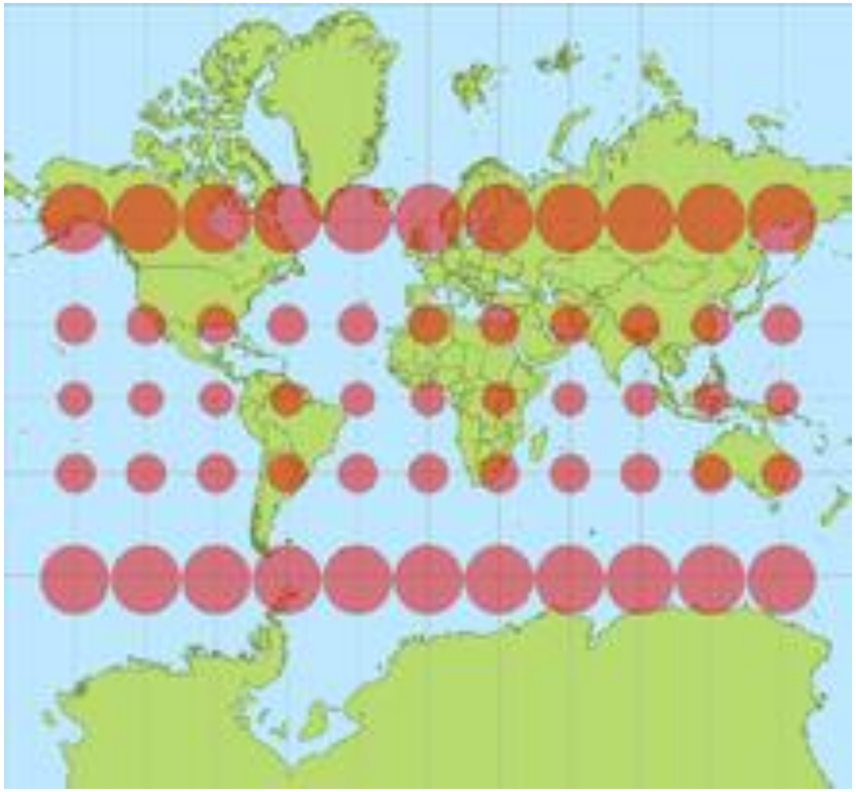
a. Shape

A projection that maintains shape is '**conformal**'

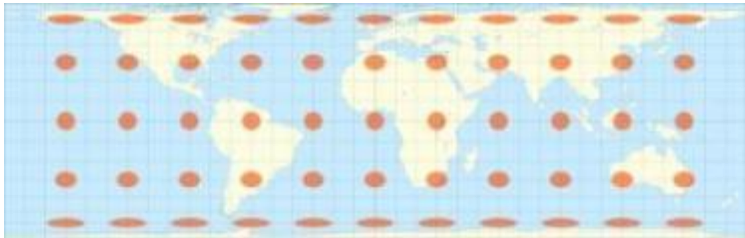
For example a 2x2 square becomes a 1x1 or 4x4 square. Stretching in one direction is **matched** by stretching in the other: that is, the scale factors are equal at a point in the two directions (i.e. there is 'equal-stretching').

Circles ("Tissot's Indicatrix") ->

These indicate the relative area compared to a standard area at the equator (the standard line)



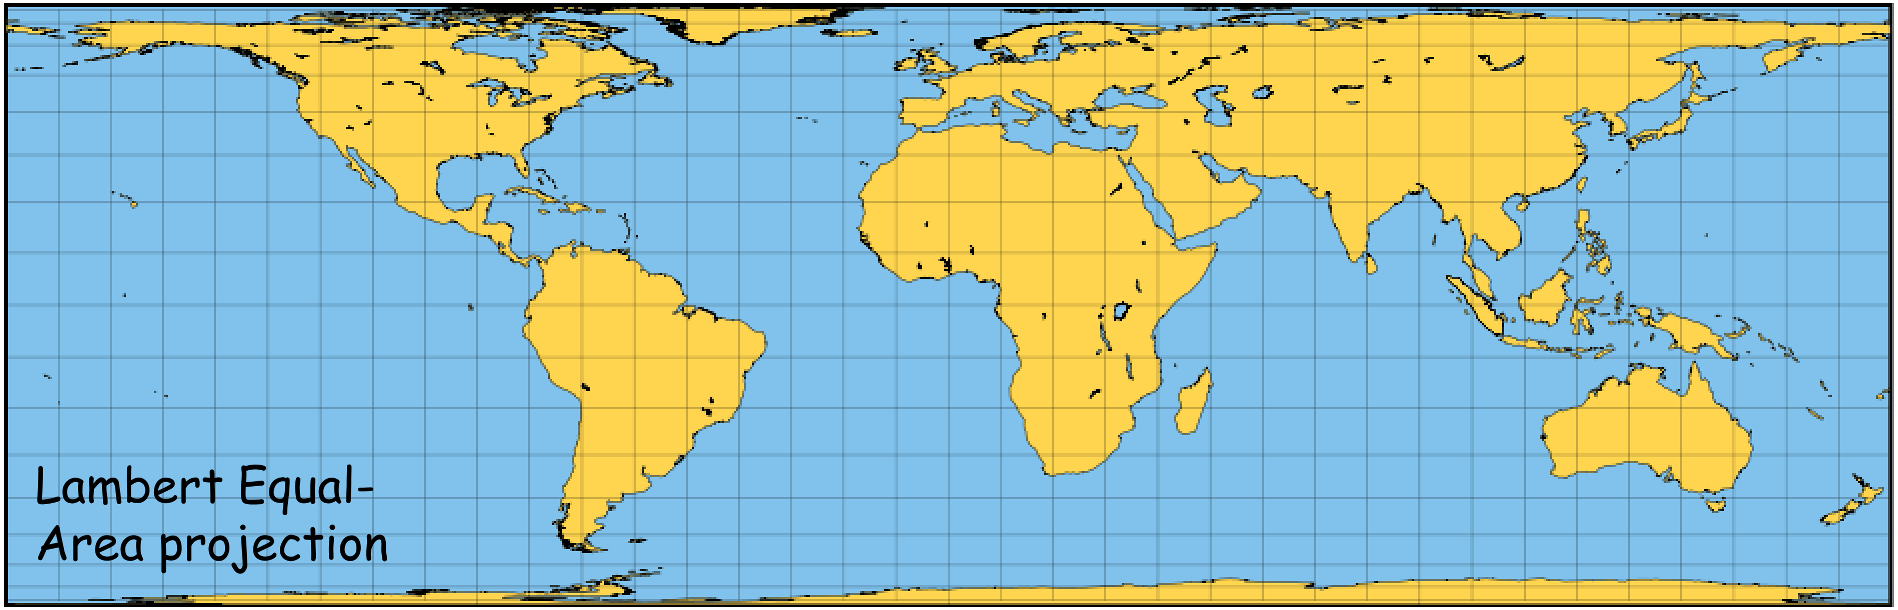
b. Area



A projection that maintains area is **equal area**

This is achieved by sacrificing **shape**: stretching in one direction to counter for earth curvature must be **compensated** by compression in the other.

In other words, the product of the two Scale factors at any point in the two directions (N-S and E-W) = 1.0 (e.g 1 x 1, 2 x 0.5 etc..)



Lambert Equal-Area projection

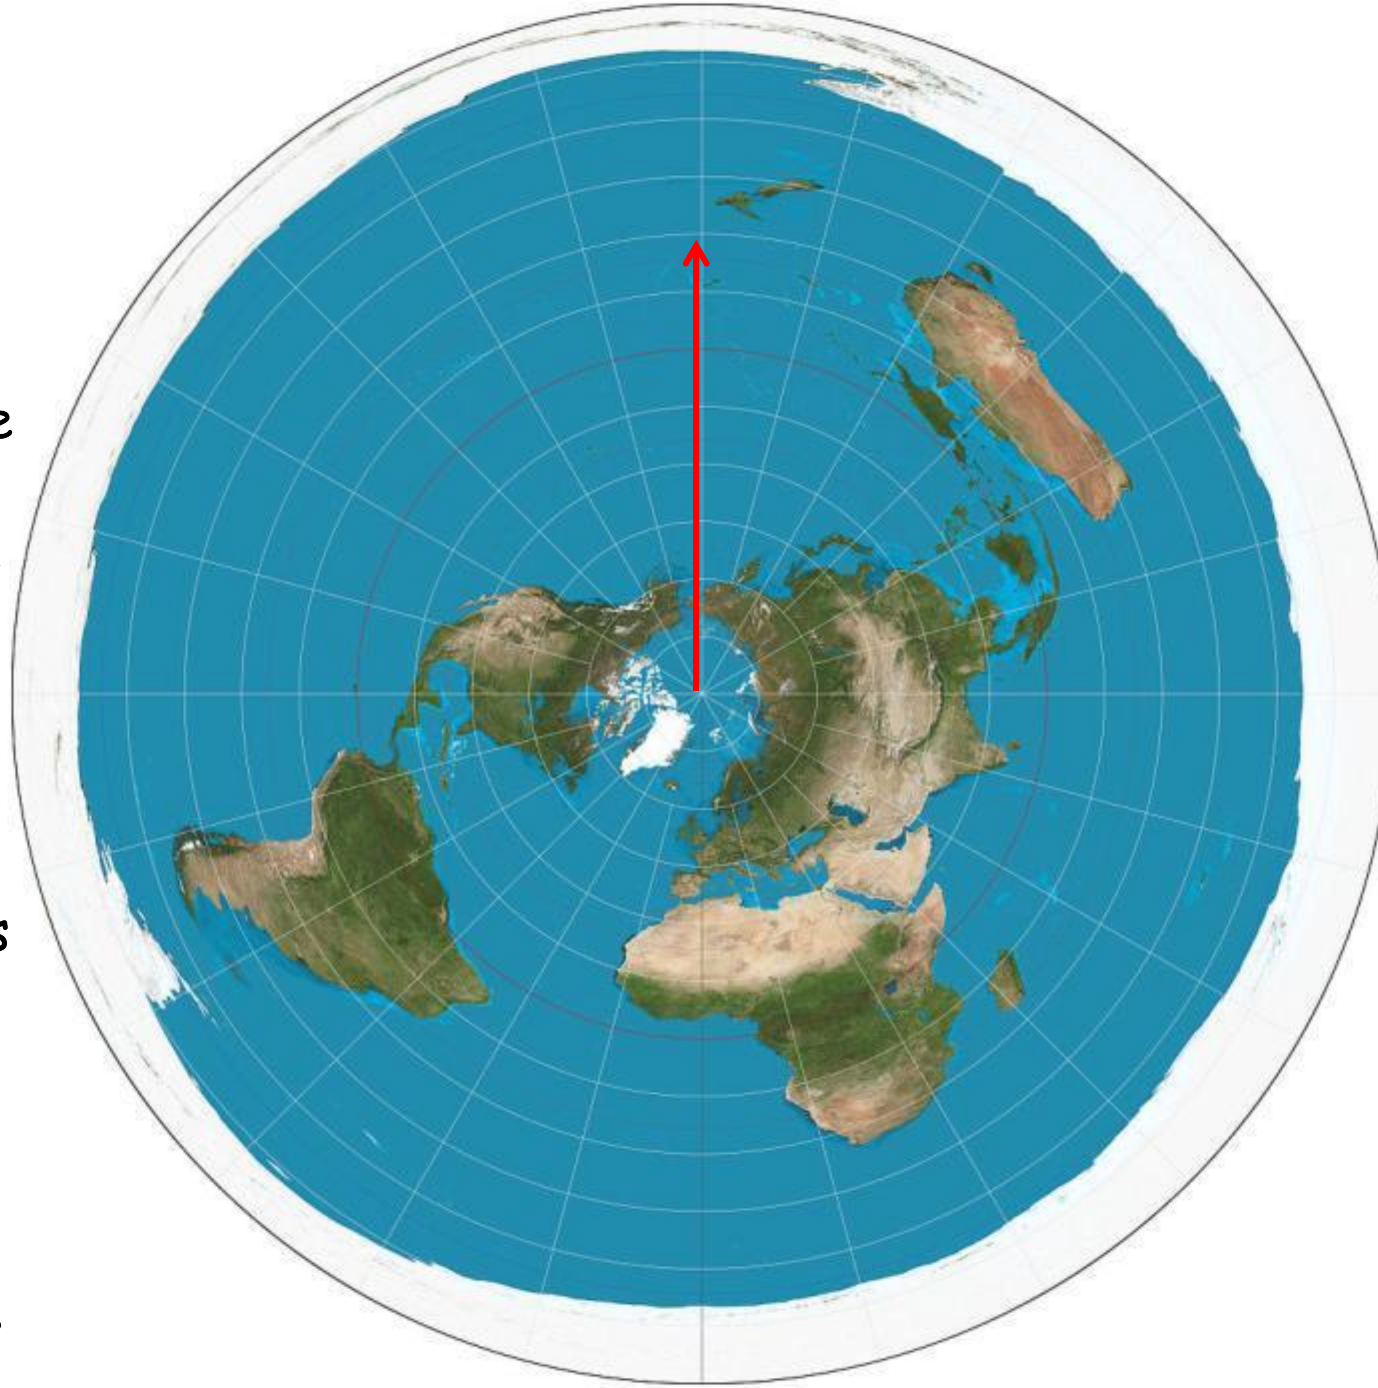
Hence a projection CANNOT preserve both shape AND area

(equal versus compensating stretching)

Projection properties: c.Distance

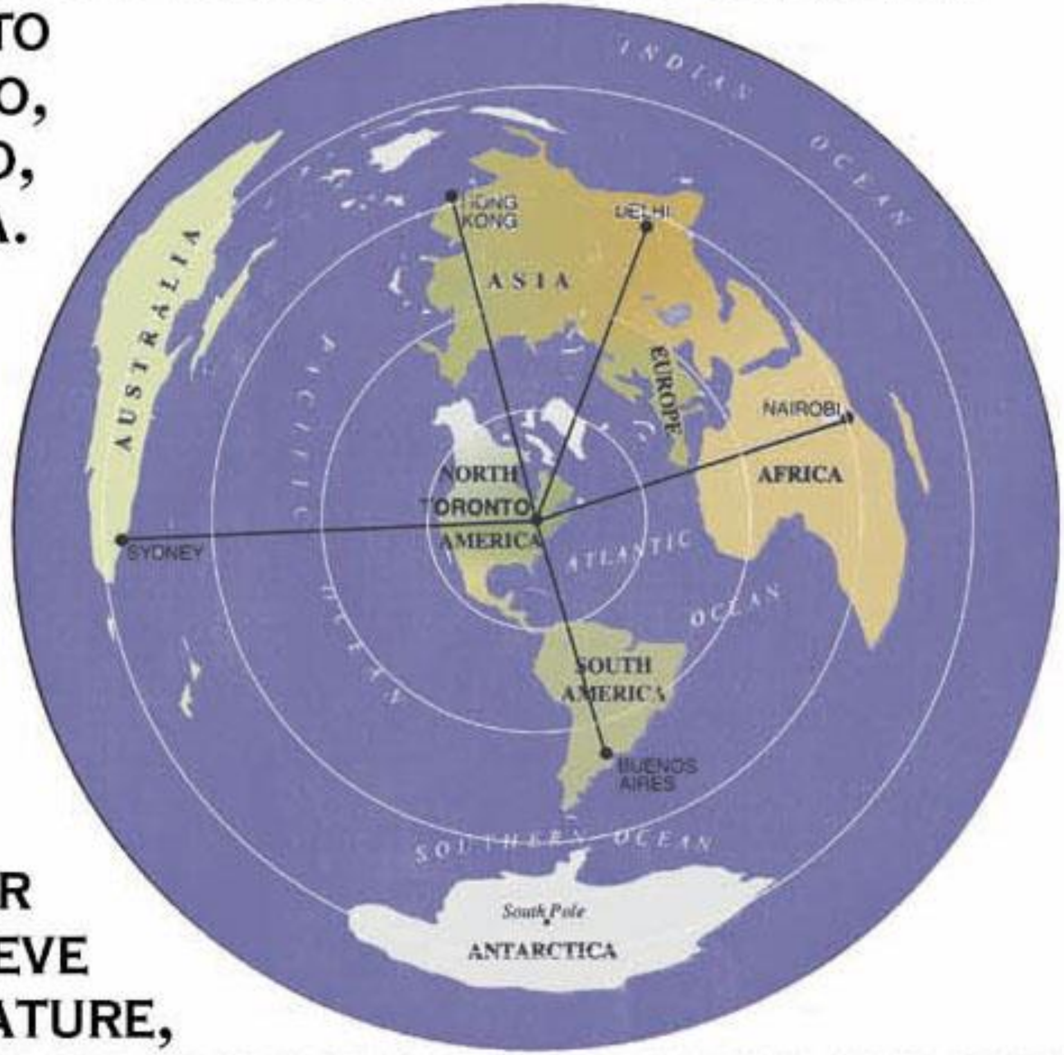
Distances can be correct in one direction from a line or in <u>all directions from a point</u>

In these cases, the projection is '**equidistant**'



Azimuthal equidistant

GUELKE'S EQUIDISTANT PROJECTION TELLS YOU EXACTLY HOW FAR IT IS FROM ANYWHERE ON EARTH TO TORONTO, ONTARIO, CANADA.

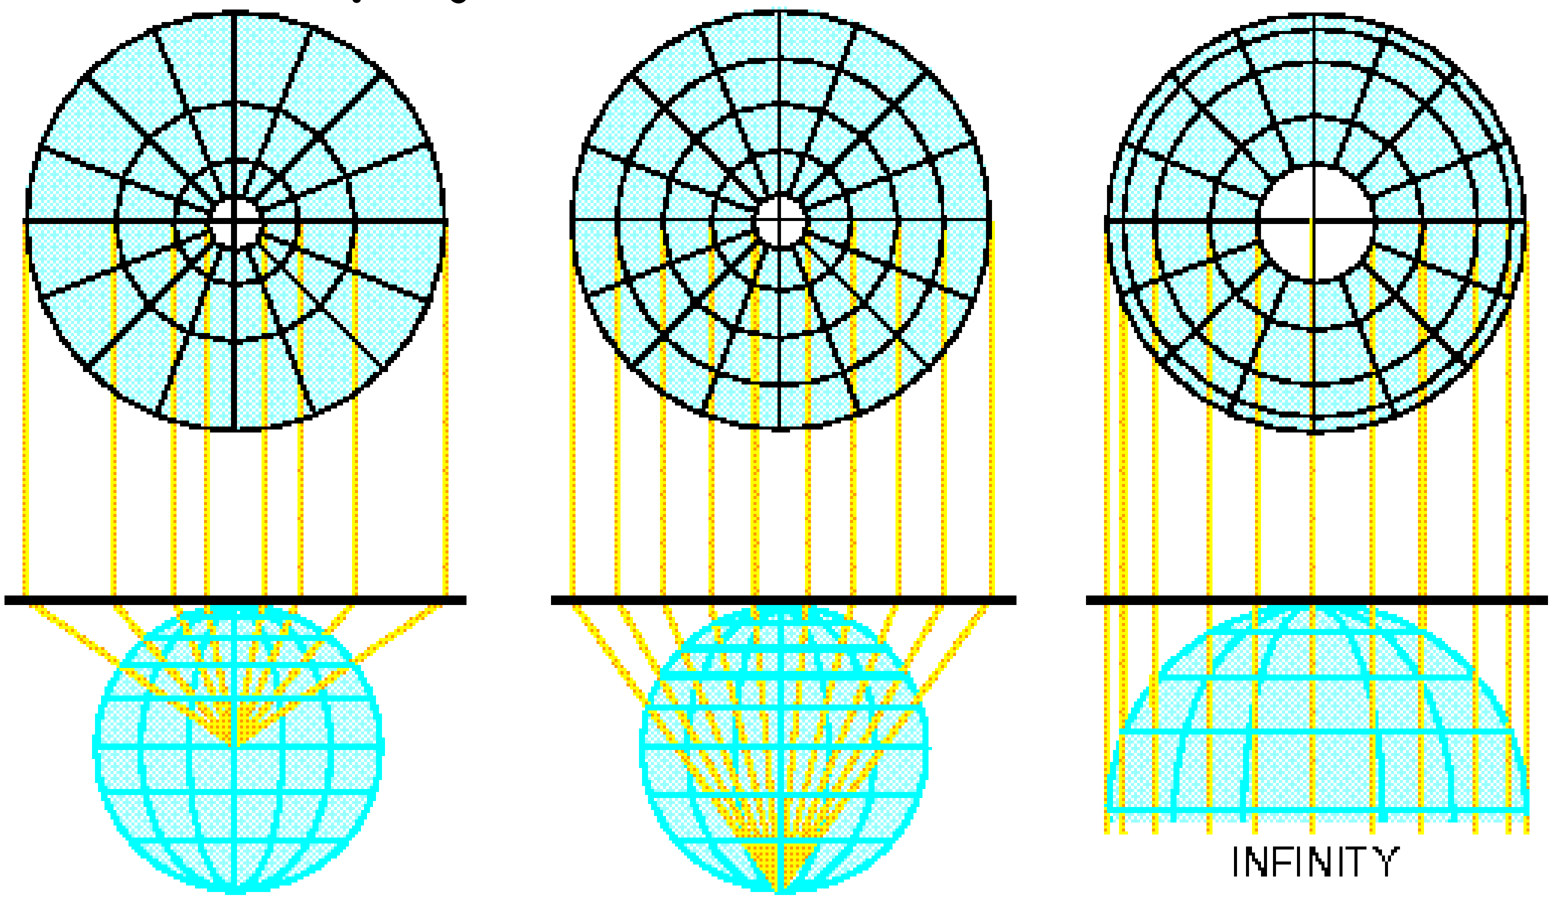


IN ORDER TO ACHIEVE THIS FEATURE, YOU NEED TO SACRIFICE SOME SHAPES AND SIZES.

www.diversophy.com/guelke.htm

Projection types (based on the developable surface)

I. Azimuthal projections



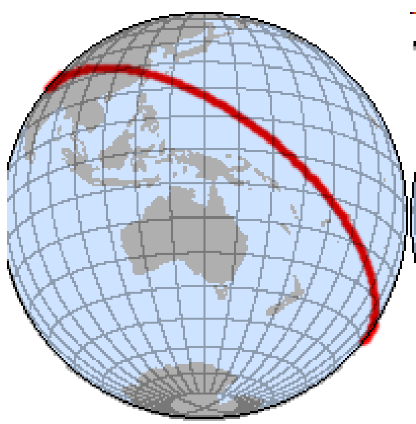
GNOMONIC	STEREOGRAPHIC	ORTHOGRAPHIC
Great circles= straight lines	Conformal (shape)	'View from space'
Thales 500BC	Ptolemy 125BC	Hipparchus 150BC

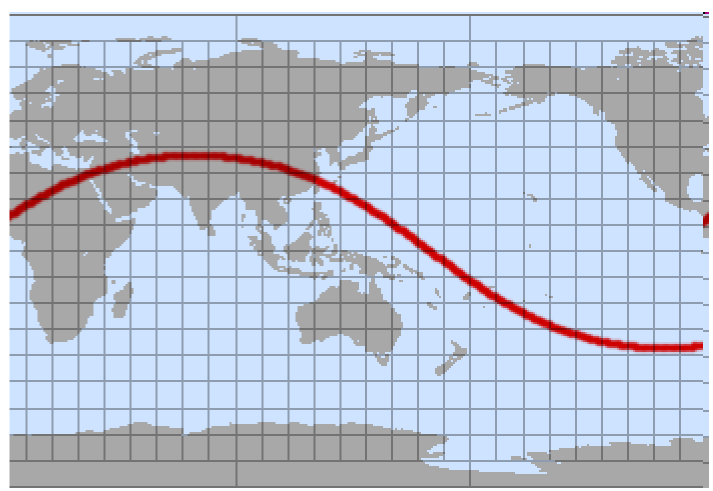
Gnomonic projection

Probably the world's oldest map projection – 6th century BC

Of all projections, only the **gnomonic** retains all great circles as straight lines

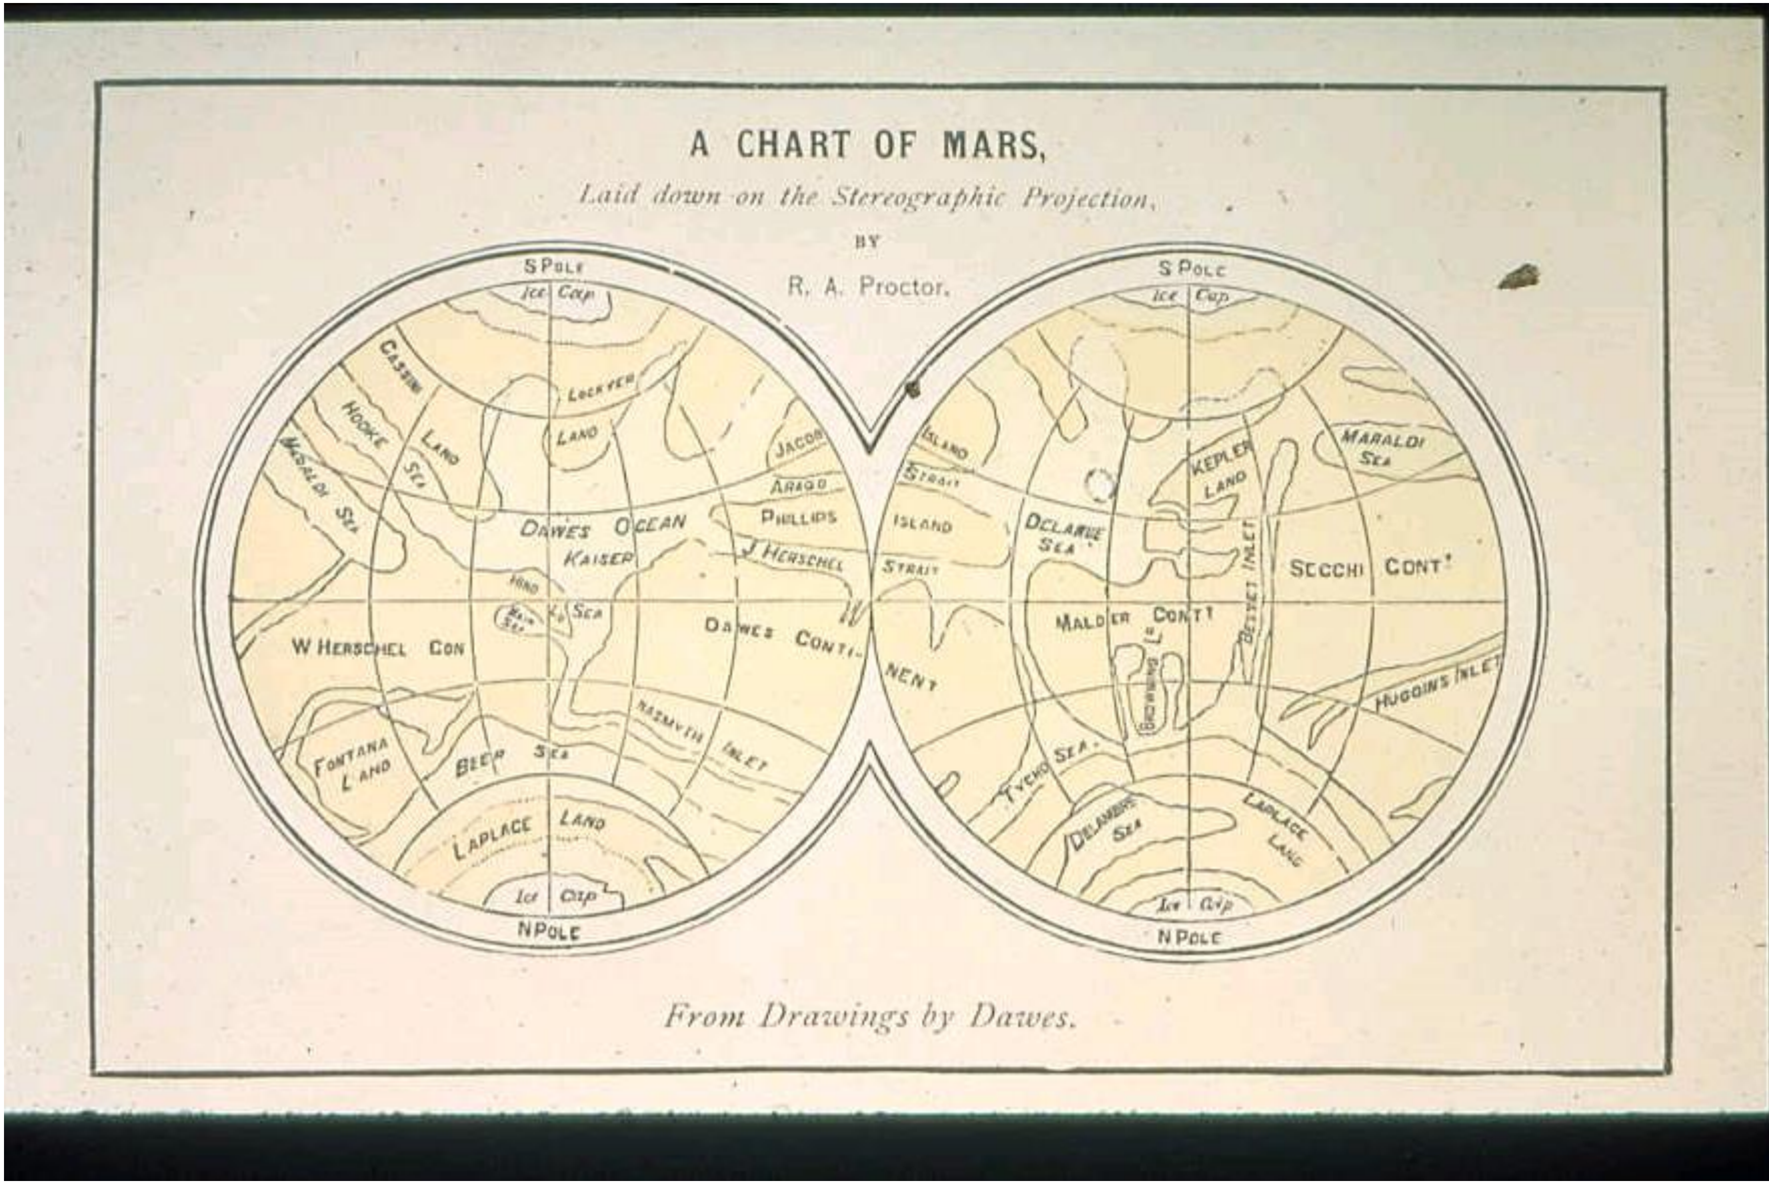
(but cannot show one entire hemisphere)





e.g. Equidistant rectangular projection

First map of Mars, 1867- equatorial stereographic

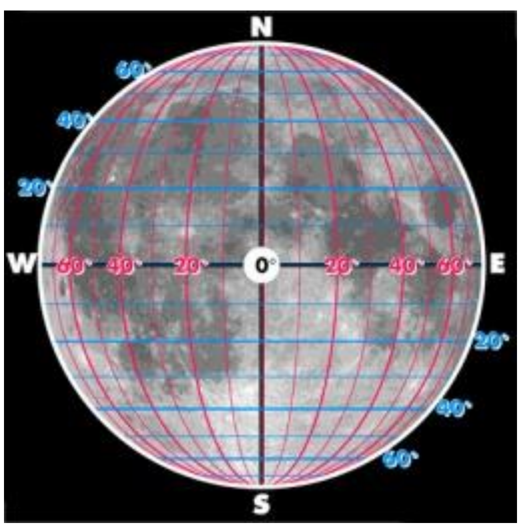


Dark / light = land / 'sea' .. Lines were called 'canals' … place names from geography

Photomosaic 1960 (pre-NASA): Orthographic projection

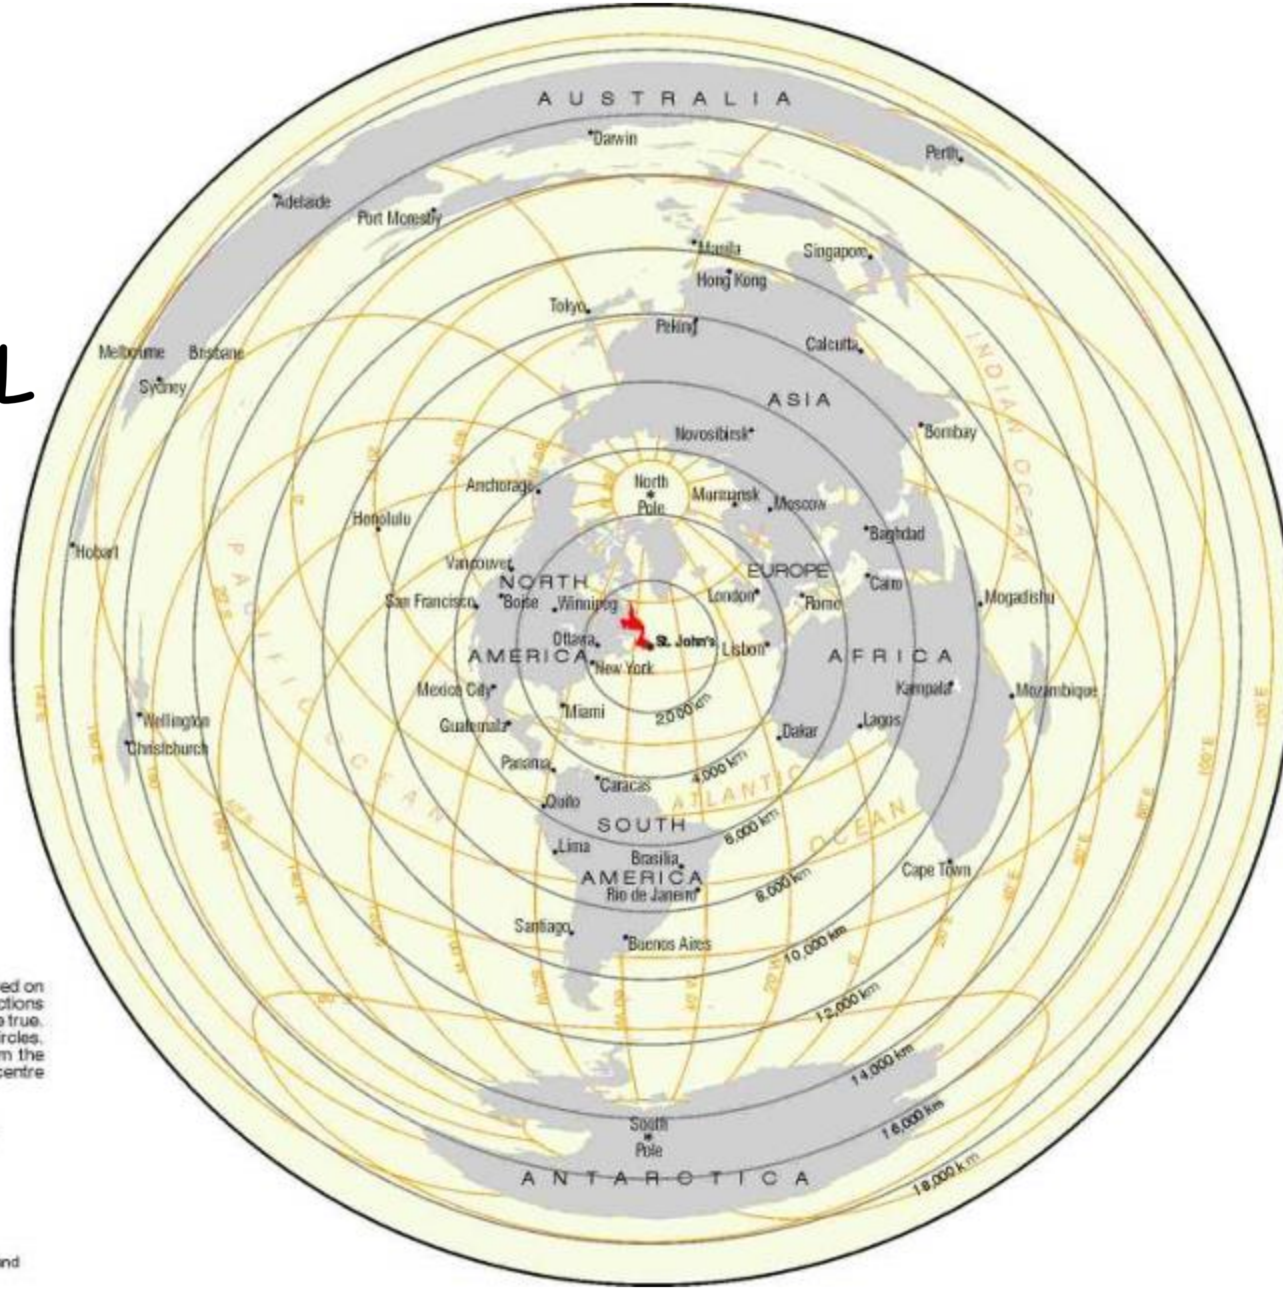
Like Earth, longitude zero is arbitrary – a feature is chosen

The Prime Meridian of the Moon lies directly in the middle of the face of the moon visible from Earth.



Azimuthal equidistant

centred on
St. John's, NL



his is an AZIMUTHAL EQUIDISTANT PROJECTION centred on
3t. John's, Newfoundland. Only distances and directions
neasured along straight lines radiating from the centre are true.
All straight lines passing through St. John's are great circles.
Deformation of the earth surface increases outward from the
centre and measurements taken other than through the centre
are inaccurate.

SCALE along any straight line through the centre

1000 0 2000 4000
Kilometres

1000 0 1000 2000 3000 4000
Miles

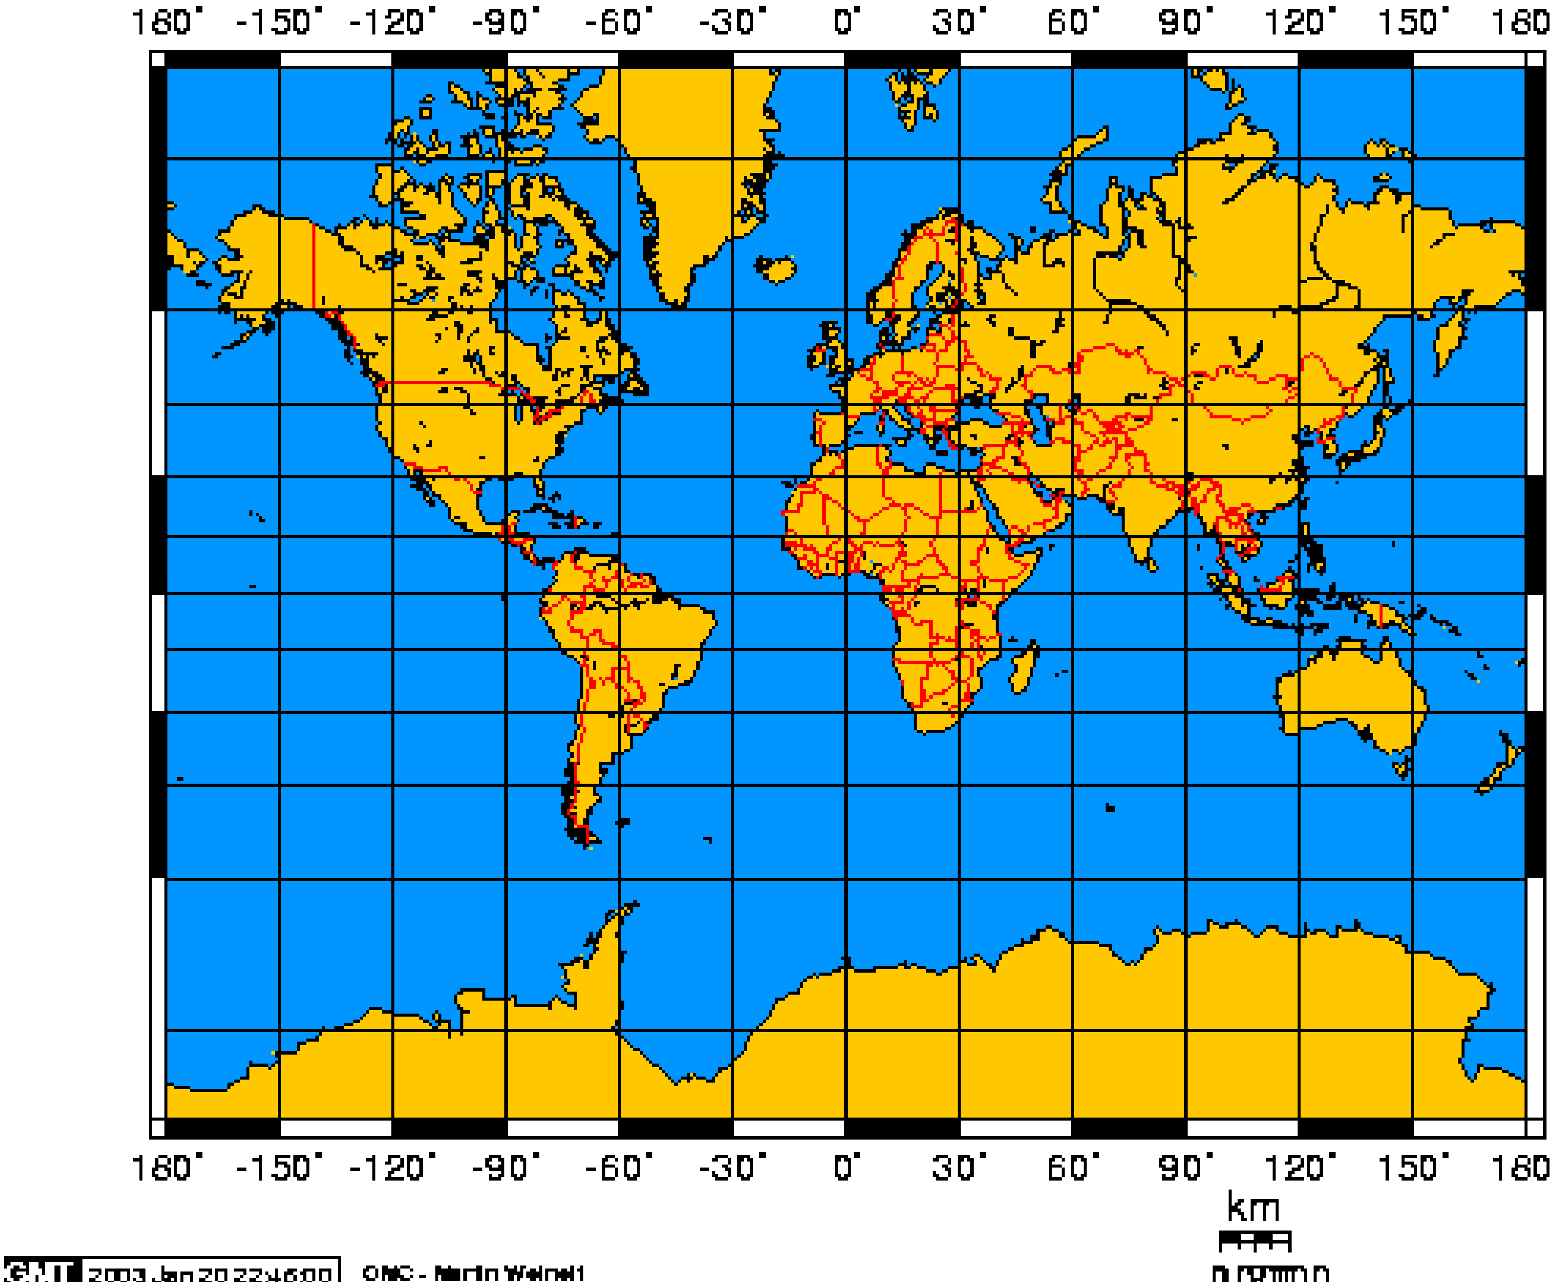
Projections of the sphere like the azimuthal equidistant projection have been co-opted as images of the flat Earth model depicting Antarctica as an ice wall surrounding a disk-shaped Earth.

The FLAT EARTH SOCIETY

II. Cylindrical Projections 16th century

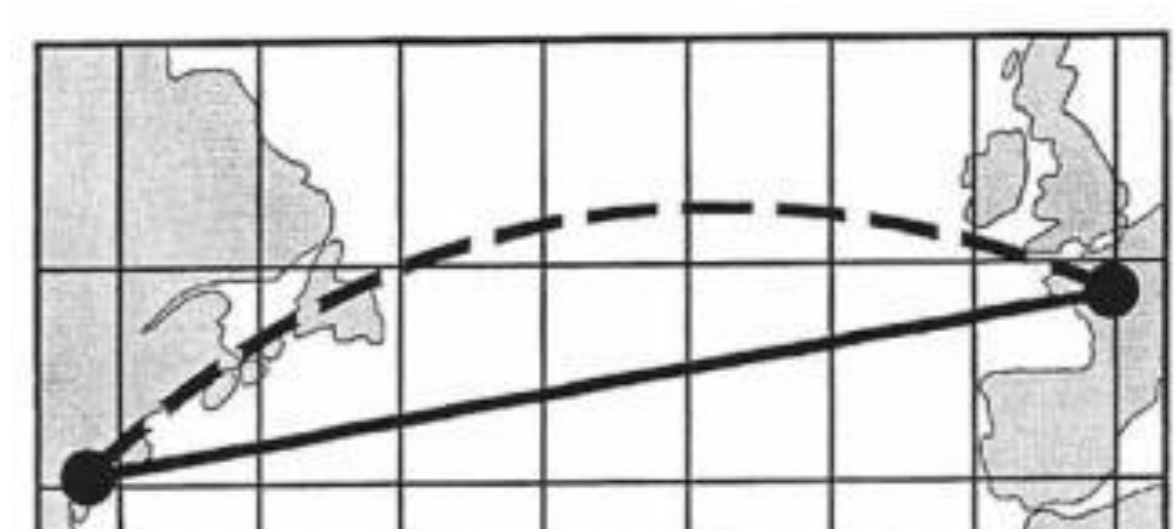
for early world maps … they fill a rectangular shape

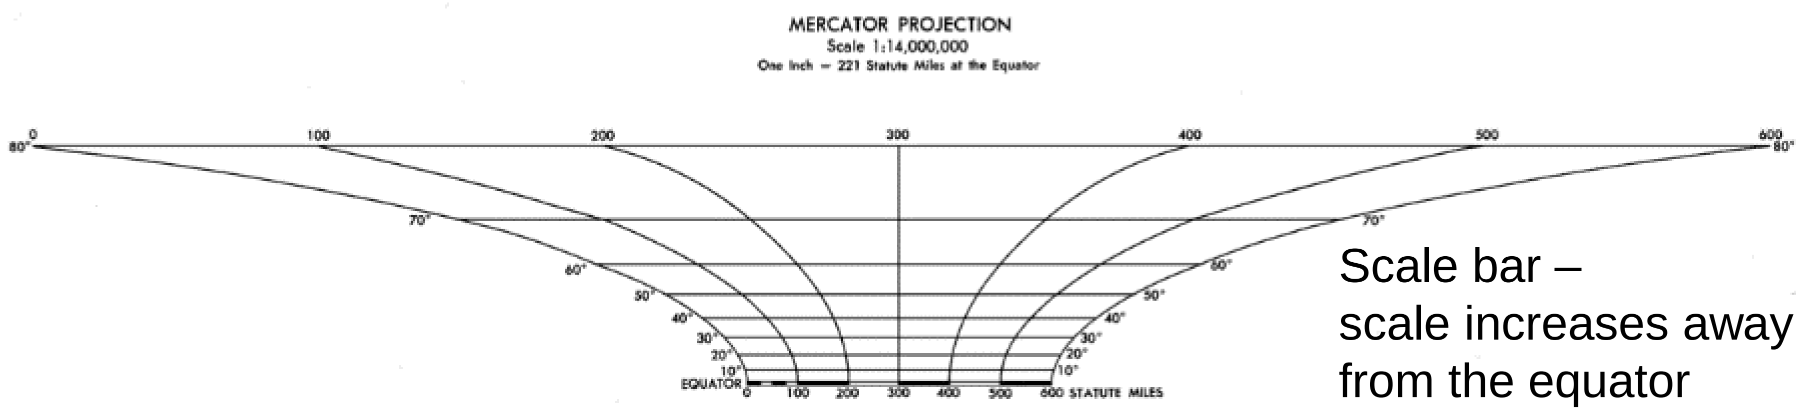
Mercator's Projection 1569 – conformal = shape-preserving



All 'straight lines' have constant compass bearings = Rhumb lines- but the dashed line (great circle) is the shortest route

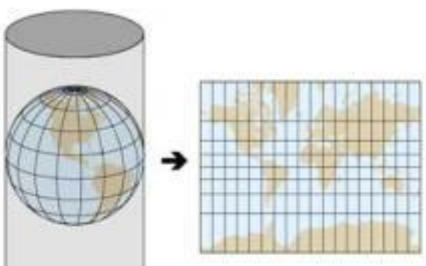
It became known as the "Navigator's friend"

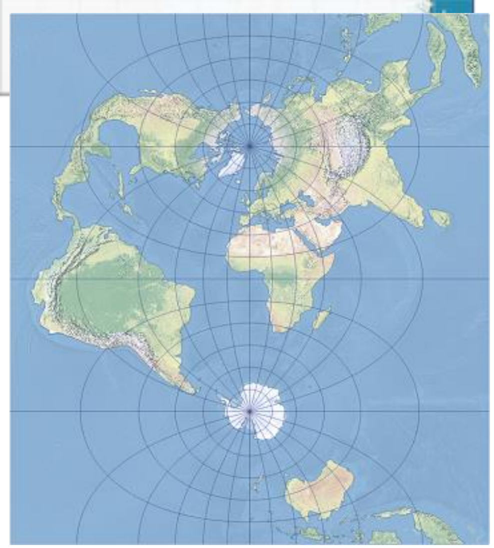




Scale bar –
scale increases away from the equator

Mercator (1569) 'normal' **Transverse Mercator (1772)**





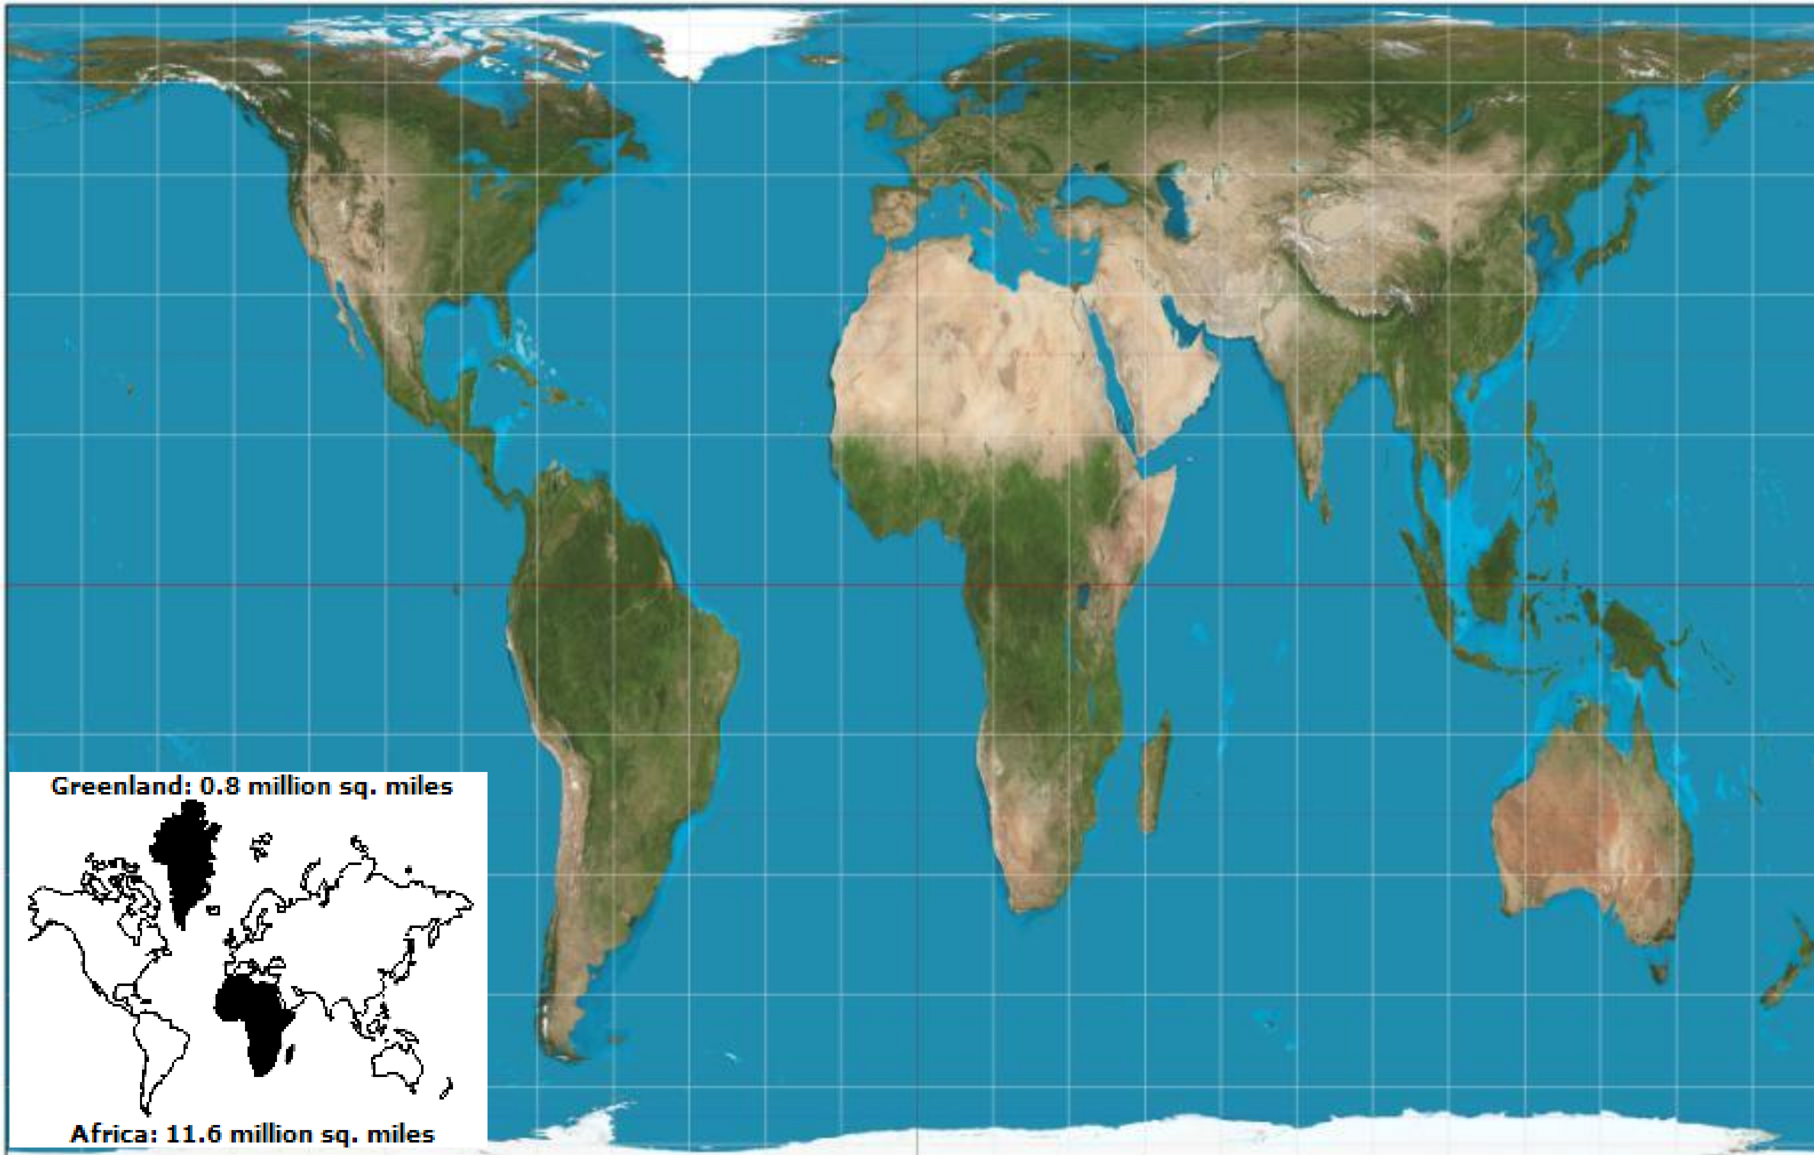
The TM projection is the basis for the (Universal) UTM system

Minimal distortion at a chosen longitude

- Adopted by Canada post WWII,
- SYSTEM of 60 TM projections

Claimed by US Army / German Wehrmacht

(1885) Gall-Peters projection (1972) – equal-area



They look the same area on Mercator

Corrects for area distortion, but note the impact on shape

III. Conic projections – 18th century

The cone opens along a line of longitude

Latitude lines are curved sections of a circle

Longitude like 'spokes' of a wheel

Can have 1 or 2 standard lines (parallels)

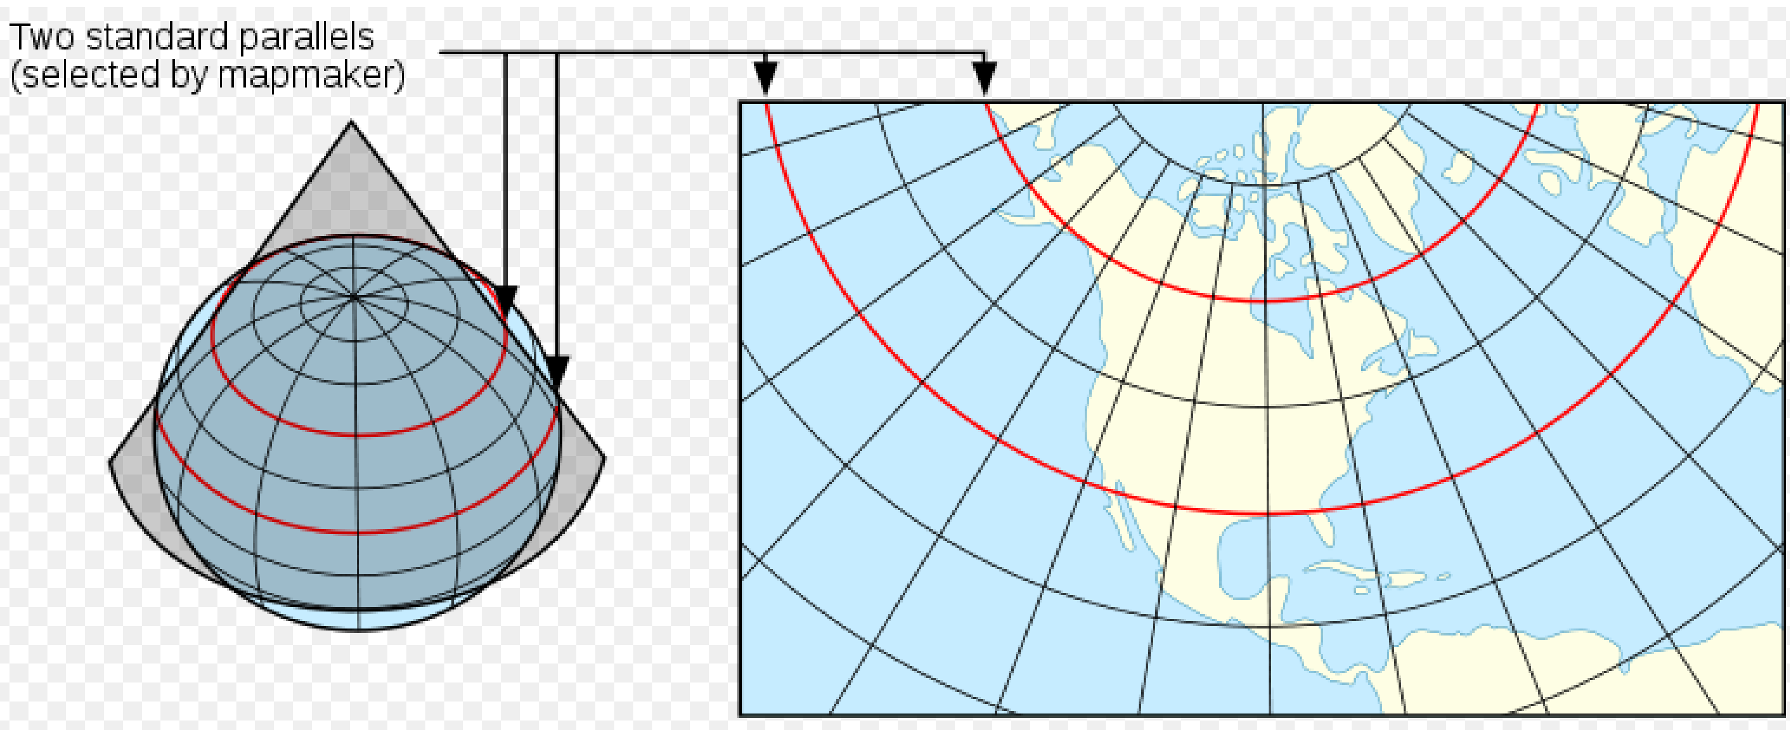
CONIC projections ... are all 'normal orientation'

(e.g. Albers)

They can be varied by :

A: angle of the cone

B: 1 or 2 standard lines



IV. Pseudo-cylindrical Projections

-19th century (and 20th) – mostly equal-area

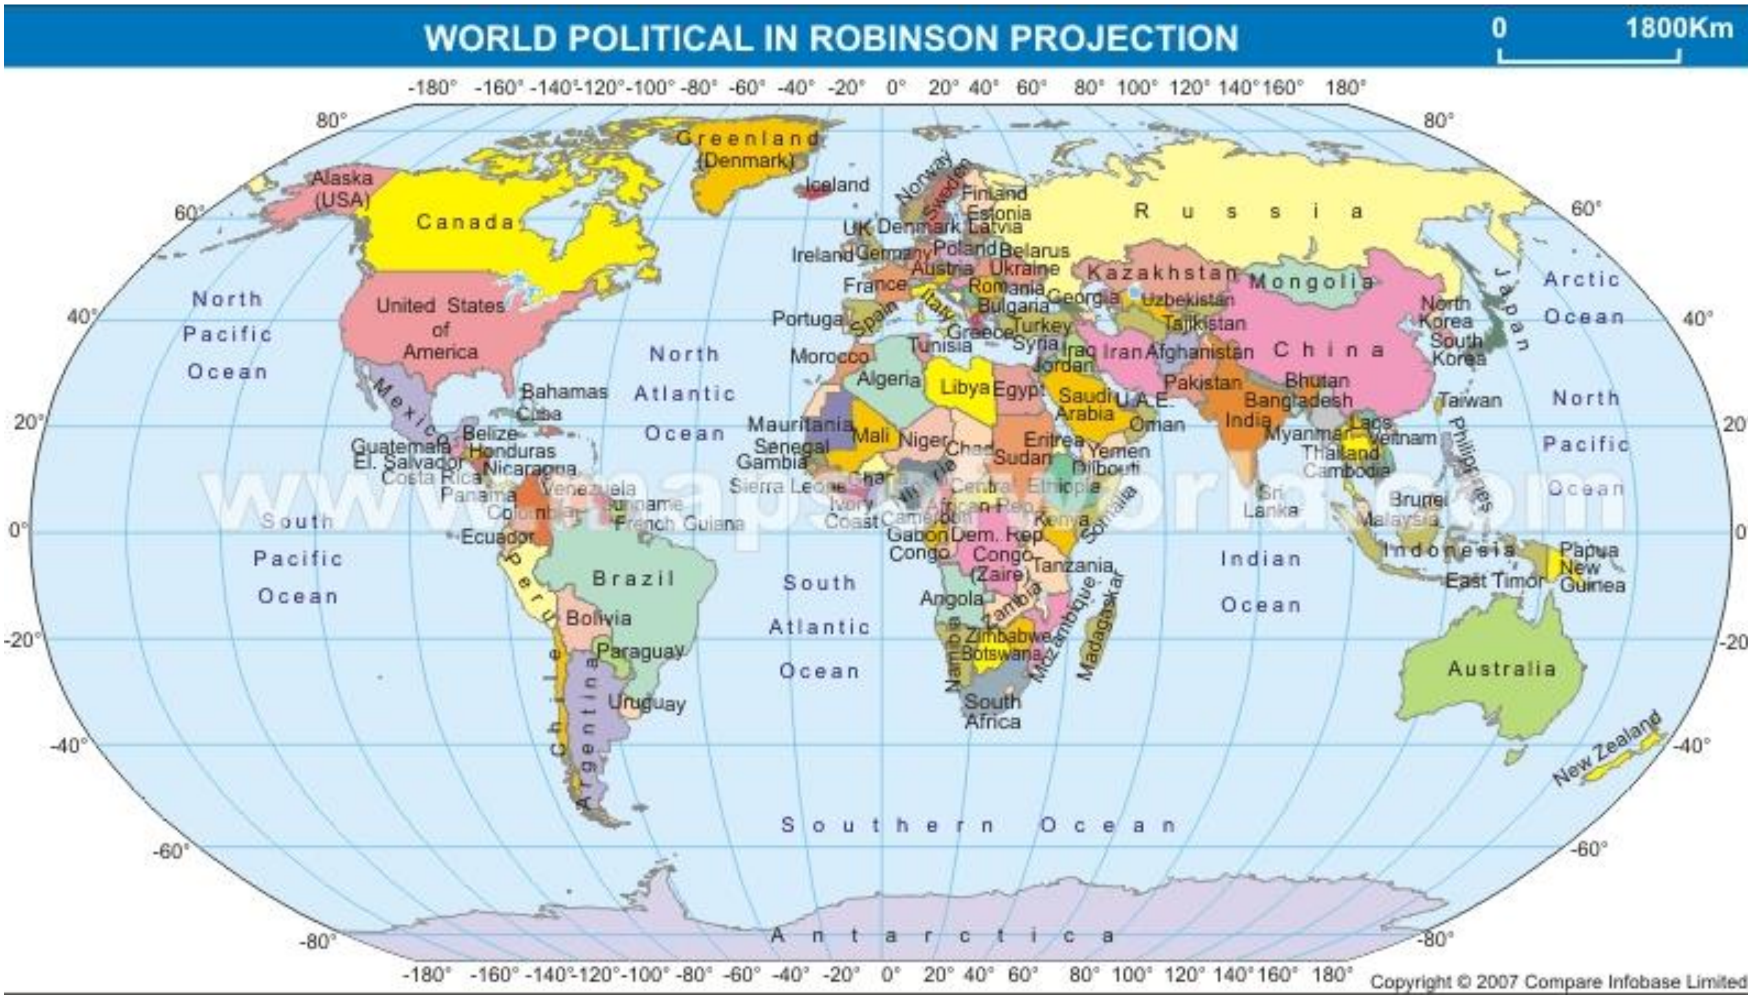
These are geometrically constructed. The parallels are generally equally spaced but are made more proportional to their real length to minimize distortion.

Mollweide, 1805

Equal area

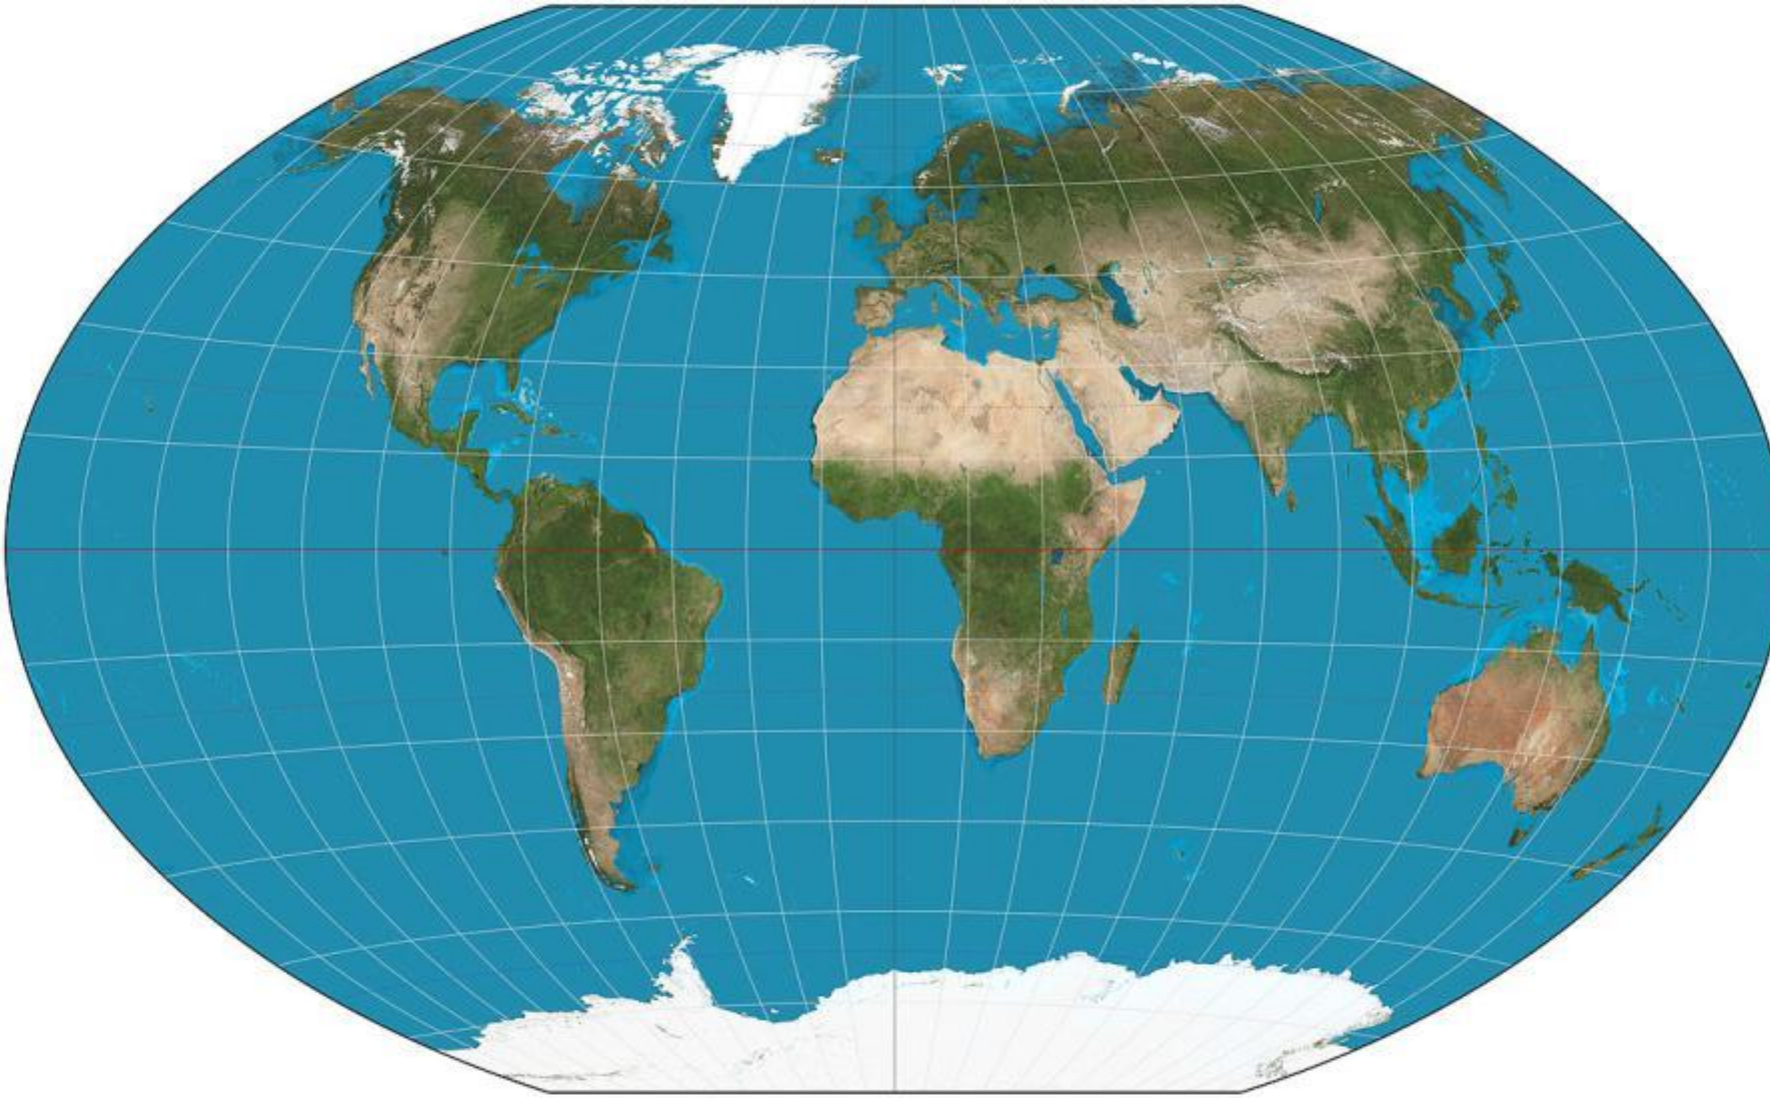
Robinson projection (1963) adopted by National Geographic 1988

Poles drawn as lines to create better shapes



http://www.mapsofworld.com/projection-maps/robinson/world-political-light.html

The **Winkel tripel (Winkel III)** by Oswald Winkel in 1921, adopted by National Geographic in 1998. The name *Tripel* refers to Winkel's goal of minimizing three kinds of distortion: area, direction (shape), and distance.



IVa. Interrupted pseudo-cylindrical (e.g. Goode's, 1923)

Minimum overall distortion and equal area – common in world atlases

And now for something completely different …
